Addresses

WHAT THE INDIVIDUAL PHYSICIAN CAN DO TO IMPROVE THE MATERIA MEDICA *

REID HUNT, M.D.
Chief, Division of Pharmacology, Hygienic Laboratory, U. S. Public Health and Marine-Hospital Service
WASHINGTON, D. C.

The subject of this address is, I believe, one of much importance to the physician, both as an individual and as a member of a learned and dignified profession, but a profession which has allowed itself to be imposed on and permitted even its dignity to be lowered and its usefulness lessened by certain influences both within and without. So much has been said in recent years on the subject of proprietary medicines that I might hesitate to bring it up again if the times did not seem so opportune for constructive work, and work in which the individual physician can and must take the leading part.

Before entering on this discussion, however, a few words may be said concerning the place of drug therapeutics in the practice of medicine. The best energies of the profession for almost a generation have been devoted to the discovery of the causes, and methods for the prevention, of disease, and to the development of surgical technic and to the improvement of diagnosis; the greatest successes have been achieved in these directions. These developments have concerned the public and certain specialties rather more directly than the general practitioner who is confronted with concrete and individual cases. The individual patients have profited by these discoveries, but not perhaps so much as has the public.

Forms of treatment other than with drugs are rapidly being developed and it is recognized that some of these methods have not received the general recognition they deserve and are not taught in the medical schools as well as is desirable. Most physicians are probably less skilled in the use of baths, diet, massage, etc., than they are in the use of drugs. And it is probable that these forms of treatment will receive full consideration before there occurs that further development of drug therapeutics for which the future seems so bright.

The important rôle drugs play in medicine is, however, frequently overlooked; it may be well to recall sometimes Naunyn's remark, that were it not for five or six drugs he would not care to be a physician at all. Surgeons especially are prone to forget the influence which drugs have had on their art. More than a century ago an eminent surgeon expressed the opinion that his specialty had almost reached the highest conceivable degree of perfection. This might have been true were it not for the lessons of asepsis learned largely from the use of antiseptic drugs and the discovery of general and local anesthetics.

The facts that there are other forms of treatment which need as careful study and teaching as that of drugs and that the field of activity of the physician in connection with the prevention of disease is ever widening are not valid arguments for neglecting drugs. They are, however, potent arguments for systematizing the study and use of the latter so that the best results may be obtained with the least expenditure of time and energy. Is this the case at the present time? An affirmative answer would imply that physicians do not begin with a handicap of ignorance and misrepresentation as to what they are using. That the profession in the past has been most shamefully imposed on in this respect is too well known to require any discussion; in the volume, "Propaganda for Reform in Proprietary Medicines," issued by the American Medical Association, will be found sufficient evidence, and the cases there quoted are only types of many.

Some seem to be under the impression that the profession is sufficiently awake to evils of the character discussed in the "Propaganda for Reform" and that deceptions such as those there exposed are no longer possible. There have undoubtedly been great improvements, but that the physician needs sources of information concerning new drugs other than the statements of those who are financially interested may easily be shown by a few examples.

It may be well to refer first to a case which has been practically settled, for the manner in which it was settled is instructive. In 1885 acetanilid, a simple chemical compound long known to chemists, was introduced into medicine. The name acetanilid is the true chemical name of the substance; it is not especially long or difficult to remember. Another name, "antifebrin," one not even suggesting the composition of the substance, was soon applied to it and has been in more or less extensive use ever since. While most physicians now know that the two names are applied to exactly the same compound, there was for years much confusion and cases are reported of eminent physicians who, not satisfied with the effects of "acetanilid," turned to "antifebrin." Every medical student must learn that the two are identical and it is often some time before he remembers whether antifebrin is another name for antipyrin or for phenacetin or for acetanilid. Even at present, when acetanilid has been included under its true name in most of the pharmacopeias of the world, if the physician turns to one of the leading handbooks supplied to him by the manufacturers he will find under antifebrin nothing to indicate that this is the same as the official acetanilid unless his knowledge of chemistry is sufficiently fresh for him to recognize the compound from its chemical formula. These two names for the same compound have already been in the medical literature of the world for nearly a generation and will continue to cause confusion and annoyance so long as the writings of this *period are read.*

---

* Address before the West Branch of the Philadelphia County Medical Society, May 14, 1909.

Scores of similar cases have occurred and are occurring at the present time. New names for old drugs are often introduced in a manner to lead the physician to suppose that a new drug is being introduced. For example, I recently received a circular on "soamin" from a leading English firm. In this it is stated that "the arylarsonate 'soamin' was first introduced at the end of 1907," and there is nothing in the circular to indicate that the same substance had been introduced by another firm several years previously under the name "atoxyl" or that the compound itself had been made in 1863 by Béchamp. A little further on in this circular I read: "The toxic symptoms noticed by continental physicians when using other arylarsonates have *not been observed with soamin." As a matter of fact,* most of the toxic symptoms noticed by continental writers were due to the same substance but under a different name.

*The history of many of the recently introduced syn*thetics is the same and is about as follows: Some manufacturer discovers in a compound long known to chemists therapeutic virtues or sometimes properties which lend themselves to commercial exploitation as therapeutic virtues. The compound itself and the methods by which it is made having long been public property the manufacturer can derive profit only if he can persuade the medical profession to prescribe it under some new trade-marked or copyrighted name invented by himself. Then in a short time the same substance is put on the market by other firms whose sole contribution is a new and often misleading name; in this way there are sometimes introduced for the same compound a dozen names often as dissimilar as human ingenuity can make them. In the confusion which results really new drugs are apt to be overlooked. Thus a short time ago an eminent American physician, not being satisfied with the results he had obtained in certain cases with "atoxyl," had, upon the advice of a well-known English practitioner, been experimenting with "soamin" (with equally unsatisfactory results); neither he nor another physician whom I met about the same time had thought it worth while to try the acetyl derivative of this substance because they were under the impression that this was "about the same as atoxyl." Yet this acetyl derivative is the result of months of work by one of the master minds in medicine (Ehrlich) and certainly well worthy of a trial.

The evil results of this pernicious practice of applying many names to the same substance does not end here, however. Other manufacturers add the "new drug" to complex mixtures, inventing still more new names or, with apparent frankness, naming the mixture after some other but unimportant ingredient. In this way physicians have been led to prescribe unwittingly some powerful habit-forming drugs.

Closely connected with this question of names is another evil—the direct introduction of powerful drugs to the laity. The attitude of the medical profession in disapproving of this practice is often misunderstood. As in so many other cases, self interest is stated to be the prime cause: Lady Montagu thought physicians would oppose the introduction of inoculation for smallpox because she did not think they had "virtue enough to destroy such a considerable branch of their revenue [from treating smallpox] for the good of mankind"; now antivaccinationists state that the profession upholds vaccination for the sake of the trifling fees. *Physicians discourage the use of powerful drugs by the* laity for the same reasons that they advocate vaccination and other measures against the spread of contagious diseases—for the good of the public. The Council on Pharmacy and Chemistry adopted as a rule that it would not approve an article advertised to the public except in the cases of foods and disinfectants; in explanation of this rule the Council states the objection to such advertising, in part, as follows, ". . . the well-known dangers of suggesting by descriptions of symptoms to the minds of the people that they are suffering from the very diseases described the dangers of an unconscious and an innocent formation of a drug habit, and the evils of harmful self-medication, including the dangers of the spread of many infectious and *contagious diseases when hidden from the physician."*

One of the most effective means of inviting or encouraging self-medication is the use of catchy, often therapeutically suggestive, names. A striking illustra*tion of the harm a layman may do himself with power*ful drugs is reported in a recent number of the *Lancet:* A man believed he had contracted syphilis and took "soamin" in increasing doses until he was severely poisoned. The physician, called in on account of the poisoning, found no indications of syphilis. This case well illustrates one of the chief dangers of self-medication —the absence of correct diagnosis. There is no reason to believe that the firm exploiting soamin had endeavored to persuade the laity to use it without medical advice, but the use of a scientific name (sodium arsanilate, for example) would probably have prevented such misuse and would at the same time convey a definite meaning to the physician.

Many firms make a practice of using names and trade packages which will lead to the introduction of their preparations to the laity as rapidly as possible. Striking illustrations of this practice have been offered by the exploitation of preparations containing hexamethylenamin as their active ingredient. By the use of therapeutically suggestive names and circulars discussing the value of the preparations in gonorrhea large numbers of the laity have been led to believe that some of these are almost specifics for this disease—which, of course, they are not. The wrong that may be done to innocent parties from a layman believing that he is effectively treating such a disease as gonorrhea need not be dwelt on. But is the physician who brings this class of preparations to the notice of the laity by prescribing hexamethylenamin under some of *these objectionable* forms any less culpable than the one who makes morphin habitués or inebriates by careless prescribing? Yet physicians are doing this daily and such preparations are advertised in most of the medical journals.

The current methods of naming new drugs not only lead to great confusion but serve as a cloak for all kinds of frauds on the physician and the public. The really new remedies, and especially the really new classes of remedies, are not so numerous but that physicians could keep fairly well informed concerning them if the essential facts were presented in a simple straightforward manner. Purely commercial interests are apparently absolutely dominant at present, so far as the nomenclature of new products is concerned, and there is little prospect of improvement until the medical profession—

or rather the individual physician—insists on being told, without any chicanery, exactly what he is asked to prescribe.

But it is not only in the matter of names that many of the even more prominent manufacturers do not deal entirely frankly with the physician and the public. A review of the literature bearing on proprietary medicines will readily show that the physician need not expect more detailed information from manufacturers than he actually insists on or demands.

That physicians have been content and have received but half truths concerning important matters is too well known to need much discussion. One illustration, of recent date, may, however, be given. Reference has already been made to a class of organic arsenic compounds which are attracting much attention. As they seem destined to attract still more interest in the future, and as many new compounds of the same class are being investigated, it was especially desirable that the first information given concerning them should be correct and complete. Yet the very first one, under the name atoxyl, was brought to the attention of the physician with an incorrect statement even as to its composition. Professor Puckner, Secretary of the Council on Pharmacy and Chemistry, seems to have been the first to discover the discrepancies between the manufacturer's statement and the truth. His results were soon confirmed by Ehrlich under the following circumstances: It had been recognized for some time that this compound had certain disadvantages and Ehrlich began a systematic and painstaking search for a derivative which would have the same therapeutic properties but which would be less toxic. He saw at once that the modification he desired to make would be impossible if the statements of the manufacturer concerning the chemistry of the substance were correct. A lesser genius than Ehrlich would probably have abandoned the attempt; Ehrlich did not and soon found, as Puckner had found, that the manufacturer's statements were not correct and that it was, after all, possible to make the derivative desired. The result was the discovery of a new compound, arsacetin, which promises to be of much value.

Illustrations such as the above could be multiplied almost indefinitely, but these are surely sufficient to show that sources of information other than that supplied by interested parties are urgently needed. Were it possible for the physician to learn promptly a new drug under a single name, and be given all that is known concerning its composition and action, he would be in a much better position to begin his clinical studies; he would have more time for careful observation and for the study of the dietetic and other forms of nonmedicinal treatment. The physician's task is sufficiently complex and difficult without the handicap of confusing names and imperfect or misleading statements concerning the drugs he uses.

While the entire method of the introduction of new drugs is far from satisfactory from the standpoint of either the physician or of the public, it is but the logical outcome of the failure of the medical schools and of medical institutions to support adequate departments of pharmacology. If every important medical school had a really efficient department of pharmacology, in which properly trained men received sufficient compensation so as not to be compelled to engage in the practice of medicine or in commercial work, but who could devote all their time to teaching and investigation, giving their results freely to the world as do the chemists and physicists in the best universities, the whole aspect of the proprietary medicine question would soon change. How fruitful university laboratories of pharmacology have been in the past is sufficiently attested by the introduction into therapeutics of chloral, of antipyrin and most of the other modern antipyretics, of cocain, of paraldehyd, sulphonal and most of the other newer hypnotics, of strophanthus, eserin, the nitrites, theobromin, the suprarenal glands, and many others.

The endowment of such pharmacologic laboratories would be a good investment for both the medical profession and the public. So long, however, as they do not exist, or are so inadequately supported, the physician must pay the toll of lost prestige and the public that of high prices for new drugs, and neither has much cause to complain. And the manufacturers who make real contributions—and there are many such—have the right to expect the physician to recognize their just claims. But neither the physician nor the public is under obligations to pay toll to the parasites who simply appropriate the discoveries of other manufacturers or of physicians themselves. There are also limits to the benefits which would be reaped by even the worthy manufacturer; for many of the discoveries of the latter are such as would inevitably soon have been made by others and no one should be allowed to secure a permanent monopoly on them.

What steps can the medical profession or, rather, what steps can the individual physician take to secure the information necessary for him to derive the best results from drugs with the least expenditure of time and energy? The answer is as old as the history of medicine itself: by cooperation to establish and maintain standards which in the last analysis shall represent the contributions the individuals make for the common good. Little patience is shown nowadays with those who hold up the past as a model for the present. Yet in the making and maintaining of standards for drugs the medical profession in this country does seem to have departed from one of its most honored traditions, but there are many indications that this departure is only temporary. Until comparatively recently the books of standards—or pharmacopeias—were the work of physicians; they represented the contributions of individual members. Through a variety of influences, some of which are difficult to determine but in which the low standards of medical education played a rôle, physicians took less part in the revision of the Pharmacopeia. With the diminished interest in revision came diminished adherence to standards; and then the Pharmacopeia came to represent less and less the needs of the medical profession. One of the earlier indications that this was the case was the preparation of the first edition of the National Formulary in 1888, by which the pharmacists endeavored to supply a book of standards for non-secret, in many cases elegant, preparations. But the physicians were abandoning more and more standards prepared by disinterested parties and accepting those of manufacturers, and, moreover, the works now prepared almost entirely by pharmacists failed to meet not only the fancied but often the real needs of the physician.

It is not necessary to trace the further history of this subject in detail or to relate the sporadic efforts made to counteract some of the evils resulting from proprietary medicines. A new era began about ten years ago when Dr. George H. Simmons was called to the editorship of THE JOURNAL of the American Medical Association. Dr. Simmons proved himself to be one of those—unfortunately few—editors who do not feel that their duties end with keeping the reading pages clean. As the result of a review of the advertising pages thousands of dollars worth of advertising was discontinued and a firm stand taken concerning the attitude of THE JOURNAL toward proprietary medicines. This required rare courage, when there was no Food and Drugs Act, when strongly intrenched and insolent proprietary interests were threatening law suits at the least suggestion that the truth be told about their products, when the timorous feared that THE JOURNAL would be wrecked, and when the medical press was hostile; but he won the battle and to-day edits the cleanest medical weekly of the world. Medical journalism does not record a more courageous course.

In the attempt to purge the advertising pages of THE JOURNAL of fraudulent products some competent and reliable authority was needed that could be referred to to decide what was right and what was wrong, especially as regards composition of the medicinal products offered to physicians. The final outcome was the formation of the Council on Pharmacy and Chemistry charged with the preparation of the book "New and Nonofficial Remedies." The purpose of this book has often been misrepresented. The authors are frequently accused of trying to dictate to the doctor or of conspiring against his freedom. The simple truth is that the American Medical Association, through the House of Delegates and Board of Trustees, has requested a number of men to serve as a committee, without remuneration of any kind, to prepare a small work on drugs which for some reason or other are not in the United States Pharmacopeia or the National Formulary. The one criterion for the admission of proprietary articles to this book is this: are they as represented; and the primary question is always, do they have the chemical composition claimed? In considering the question whether the drugs are as represented the Council is frequently confronted with a dozen preparations of the same class claiming to be "absolutely the best"; thus there are about a dozen of the "most powerful" but "least toxic" germicides, a dozen or more of "absolutely the most powerful" diastases; quite a number of the "safest" hypnotics and so on. Evidently some of the gentlemen making these claims are mistaken and the Council has asked "to be shown." Some firms have admitted that their statements were incorrect and have changed them to correspond to the facts; others have admitted that their claims were false but stated that they would try to make products corresponding to them in the future, but that in the meanwhile they could not afford to injure their standing with the physicians by telling the truth; still others have stated that it is none of the physicians' business whether the truth is told them or not. As a rule no further attention is paid to these latter classes of products; occasionally one of them is exposed as an example of the kinds and varieties of frauds that are being practiced, but the Council desires its work to be constructive and not destructive.

The Council has found that there is a large and increasing number of physicians who desire information such as the Council attempts to collect; this desire comes partly from a fuller realization that a physician should neglect no opportunity to be certain of the composition of the drugs he uses. As a concrete example of the deception that may be practiced unwittingly I may refer to a preparation claimed to be a solution of mercuric iodid in an oil suitable for hypodermic injection in syphilis. Dr. Seidell examined a sample of this preparation in the Hygienic Laboratory; not a trace of mercuric iodid could be found. A second sample, of a lot made in the presence of a medical practitioner who weighed the mercuric iodid himself and saw it added to the oil, was also found to contain no mercuric iodid. We do not know in what stage of the process the drug was lost, whether by volatilization, by filtration or how; we do know, however, that it was not in the preparation which reached the physicians—as indeed the clinical results of some of the latter showed. Would not a physician who had used such a preparation in a critical case of syphilis and lost his patient feel as guilty as if he had made any other kind of a fatal mistake in prescribing, and might he not be liable in a court of law? The Council desires to give physicians information which will prevent such possibilities as this. There is a rather large number of physicians who resent having lies told to them about drugs, just as the self-respecting man in any other walk of life resents a lie. There are also those who are weary of having chemists, pharmacists, and other laymen (in one case a piano salesman) endeavoring to teach them therapeutics. There are others, again, who are becoming impatient of having the same drug presented to them under a variety of meaningless or misleading names. There is also a large number who do not care especially whether the absence of mercuric iodid, pepsin, cod-liver oil, iodin, quinin, etc., in so-called preparations of these drugs is due to incompetency or knavery but who do want some evidence of their presence in addition to that of individuals financially interested. The Council is endeavoring to make "New and Nonofficial Remedies" a work of standards for such physicians as these and it invites, as it has from the beginning, the cooperation of all.

Soon after the Council began its work an endeavor was made to arouse the antagonism of manufacturers on the ground that their property rights were being attacked. Not many of these, however, have had the hardihood to ask physicians to use their preparations and at the same time to tell them that it was none of their affairs what these contain. On the contrary, many have found it good policy not only to state the composition but to state how this may be verified by other chemists, just as the Pharmacopeia gives tests of identity and purity for the various products contained in it. I know of no physicians or editors of medical journals who deny the necessity for work such as the Council is doing. It has, however, bitter enemies. One of the leaders of these stated that it was folly to attack the American Medical Association or the Council on Pharmacy and Chemistry directly; and that the only chance of checking the work of the latter was to attack the members personally. Dr. Simmons, as Chairman of the Council and as editor of THE JOURNAL which has led in the movement, has been the subject of most frequent and persistent attack. Most of the recent ones, some of which are anonymous, can be traced directly to those who are financially interested, in one way or another, in proprietary medicines. It is scarcely necessary to consider these; a glance at the advertising pages of the medical, or rather pseudomedical, journals containing some of them, or a moment's consideration of the editors' commercial affiliations, will suffice to disclose the animus.

The incompetency or insincerity of some of the manufacturer-editors, who, till recently at least, were most persistent in these attacks and who pose as working for the uplift of the profession, may be illustrated by a concrete example which came to my attention. Dr. Seidell and I examined some time ago in the Hygienic Laboratory a number of samples of a solution of nuclein exploited by a company whose fervent appeal for a "square deal" is known to many of the physicians of the country. Here are a few typical statements from a circular issued at that time by the firm: "For years we have been the chief promoters of nuclein therapy, endeavoring to place its principles before the profession in the right light—in a practical, usable form and as far as possible deprived of all uncertainty. Out of our experimental work we have developed the chemistry of nuclein to a point that produces a product second to none." They stated that their nuclein was "all right;" that it had the unqualified endorsement of "hundreds and thousands" of physicians well able to judge by results; that they believed it to be far the best product on the market, etc. The following is said as to its dosage: "It should be remembered that, except in acute toxemias, over-stimulation of the cells is not to be desired; therefore, in low states of vitality, small doses (gtts. 2-5), long continued, give best results. In all acute invasions of the system LARGE DOSES (gtts. x-xx, preferably hypodermically) are, however, necessary. These should be repeated at least twice daily. In emergencies, where the patient is overwhelmed with toxins, the exhibition should be made every few hours." Our examination of the solution thus described in such enthusiastic terms showed the presence of from 0.04 to 0.05 per cent. of solids (about the amount present and permitted in many potable waters). Assuming these solids to have consisted entirely of nuclein (a rather rash assumption perhaps) the usual dose of the solution recommended would have contained from 1/400 to 1/1300 of a grain of nuclein. If the dose were repeated about a dozen times a day the patient would in the course of a month have received nearly a grain of nuclein—an amount obtained several times over in any ordinary single meal. If the case were desperate—if, as the circular states, "the patient were overwhelmed with toxins"—and, following the directions, large doses (gtts. x-xx) were given hypodermically, it would have required about 100 hypodermic injections to introduce a grain of nuclein. Why not give the patient a bite of sweetbread? It would have contained as much nuclein and been more agreeable. The difference in price might be a factor; for, while sweetbreads are somewhat expensive, fifty times the price of pure gold was asked for the nuclein in this solution. The crushing reply to such suggestions would probably have been, quoting from the circular: "This nuclein is all right. It has the unqualified endorsement of our Drs. . . . as well as hundreds and thousands of others well able to judge by results." Seriously, has not such so-called clinical evidence about the value of that of physicians who a few years ago were "curing" malaria with powdered gypsum sold under the name "tasteless quinin" or of the laity who "cure" measles with sheep dung? And think of wasting valuable time in the case of serious illness experimenting with such stuff. The company exploiting this nuclein took the commendable step of practically withdrawing it from the market until they learn something about the subject; but what are the "hundreds and thousands" who obtained such good results with the old preparation doing in the meanwhile?[1]

Will the medical profession allow itself to be influenced by criticisms coming from such sources as the above? And nearly all the criticisms of Dr. Simmons and of the Council have come from exactly such sources and similar interests closely allied, commercially, with them.

Before leaving this subject a word may be said concerning the attitude of many medical journals toward secret proprietary medicines. Disappointment is frequently expressed that so many of these continue to accept the advertisements of preparations which have been shown clearly to be fraudulent. It is unquestionably humiliating to see that the standards of so many medical journals, in this respect, are decidedly lower than those of some other professional journals and of many of the popular magazines. Still, an improvement is very noticeable; a sharper distinction has been made between the reading and advertising pages and several have dropped some of the most objectionable advertisements altogether. The editors of many have become apologetic. Some say they would like to reform but will not be dictated to; like Falstaff, they will not tell the truth on compulsion. One editor remarked that some of the advertisements in his paper were so evidently frauds that nobody could be deceived! As regards those journals which are published simply as business enterprises and in which there is a real division between the provinces of editor and advertising manager, the profession may as well accept this fact: Dishonestly exploited drugs will be advertised so long as there are doctors to use them or so long as doctors subscribe for such journals. The fact may be deplored, but it will remain a fact. The case is different with the journals supported by medical organizations. An organization which can not support a journal which is clean from cover to cover should not try to publish one at all. At present the advertising pages of the *Military Surgeon,* the official organ of the Association of Military Surgeons, are a striking example of what should not be tolerated in a journal controlled by a body of medical men; it is to be hoped that the new management will make radical changes.

Instances could be multiplied almost indefinitely of how secret or semisecret proprietary medicines stand in the way of progress. Many physicians in their zeal to give their patients the benefit of the latest discoveries are prescribing preparations which contain practically no medicinal ingredients at all or only the old familiar drugs under a new name. The remedy is to turn to the practice of using only those drugs, the composition of which has been determined by physicians or by their representatives.

Of the standards at present available the United States Pharmacopeia is, of course, the best. By the enactment of pure drug laws by the United States and by the several states this has practically become the national standard. Where there is the proper cooperation between physicians, pharmacists and officials entrusted with the enforcement of pure drug laws the difference between the value of official and proprietary preparations is about as great as that between the legal currency and the promissory notes of Tom, Dick or Harry; those of Tom may be all right, but the probabilities are that those of Dick or Harry have not their face value. Hence one of the first duties of the physician is to adhere as closely as possible to the preparations of the Pharmacopeia. A little study or consultation with one of those truly professional pharmacists who are to be found in almost every community will convince many a physician that he is using drugs for which officially recognized ones may easily be substituted. If, however, after careful study, he fails to find in the Pharmacopeia or in the case of a pharmaceutical mixture, in the National Formulary, the drug he desires to use, I believe the next best source of information is New and Nonofficial Remedies. The latter contain, in the case of proprietary preparations, not only the statements of the manufacturers, but also the results of the investigations of disinterested parties made by the authority of the American Medical Association. It is a noteworthy fact that of the several hundred preparations admitted to this book not a single one has been shown to have a composition differing from that given, whereas the larger part of the proprietary preparations at present on the American market which have not been admitted to New and Nonofficial Remedies have been found to be of uncertain or variable composition or exploited in a questionable manner. Hence a physician should be very cautious in using a drug which is not contained in one of the above-named books. If, however, after careful investigations he is convinced that he has found a drug of value which has not been admitted to these works he is false to the traditions of his profession if he does not make the fact known to his colleagues. It would be safer, however, for him first to submit his findings to the secretary of the Council on Pharmacy and Chemistry, Professor Puckner, who probably has a more encyclopedic knowledge of new drugs than any other man in the world. Professor Puckner, as secretary of the Council, has from the first requested such suggestions as well as criticisms of the products contained in New and Nonofficial Remedies. If more such requests were sent than he could answer it would pay the profession to provide additional assistants for him. The office of The Journal of the American Medical Association should continue to be, as it is at present, a trustworthy source of information to physicians generally as well as to the members of the Association.

---

[1] "Nuclein" has frequently been a source of confusion and misrepresentation in the "literature" of proprietary medicines. In strictly scientific literature the physician reads how Loewi administered thirty grams (450 grains) pure nucleic acid to a man without observing any ill effects. From this a physician would infer that ordinarily, at least, nuclein is a harmless substance. Another proprietary preparation with the innocently sounding name "Protonuclein" was found, however, to contain considerable thyroid. There was recently placed on the market another secret proprietary product, Iodonucleoids, purporting to be a compound of iodin and nuclein. To a physician who is at all familiar with the subject of the nucleins a compound of iodin and nuclein would appeal as something new and worthy of trial. On examination, however, this preparation was found not to contain a true nuclein at all, but seemed to be a product such as can easily be made by simply evaporating a solution of hydriodic acid with ordinary casein.

By far the larger number of drugs used by most physicians are those recognized by the above standards, but, on the other hand, there are not many physicians who do not use at least a few drugs of questionable character. It is the sum total of the latter which is largely responsible for the present unscientific and unsatisfactory state of drug therapeutics. Most proprietary remedies are sold at such a large profit that a comparatively few orders will keep one of them alive. If each individual physician would carefully consider the drugs he uses and then either abandon those which are not official or are not contained in New and Nonofficial Remedies, or, if convinced that they are of value, use his endeavors to get them admitted to these works (the door of the New and Nonofficial Remedies is always open for honestly exploited drugs) much would be done to solve the proprietary medicine problem. The ideal condition will be reached only when every drug which the physician needs has been admitted to the final legal standard—the United States Pharmacopeia—and the physician should consider it one of his duties—to his patients, to his colleagues and to the public as well as himself—to use his influence to perfect and maintain this great work. The opportunity to support the Pharmacopeia comes to the physician every day; the opportunity to make his influence felt in its revision comes to him but a few times in his life. One of these times is now approaching. The Convention which meets in Washington next spring will formulate the plan of the Pharmacopeia which will be the great guide for the next decade. It is the duty of every physician to endeavor to have his state medical society and his alma mater represented at this convention by three (the number each such organization is entitled to) earnest, broad-minded men who will insist that, among the multitudinous interests seeking recognition, those of the physician and his patient will not be overlooked.

Finally, I desire to put in a plea for the support by the physician of research work in pharmacology. For thousands of years the great contributions to materia medica came from the medical profession; in the last few years only have they been coming more and more from without. The profession has lost prestige and in addition has become confronted with the proprietary-medicine problem. The solution is for the contributions to, as well as the control of, new drugs to come from the pharmacologic laboratories of the medical schools, of the Government and of medical associations. Nothing is so potent, not only for positive progress, but for dispelling darkness, as a great discovery.

CERTAIN IDEALS OF MEDICAL EDUCATION

CHARLES S. MINOT, LL.D., D.Sc.
BOSTON

It is the function of the teacher to perpetuate, by transmission to the on-coming generation, the knowledge and traditions on which civilization is based. We who have for our share of this indispensable work the transmission of medical knowledge and of medical traditions find the difficulties of getting our freight into the depots of youthful minds always numerous and often great. We, therefore, are constantly busy with efforts to improve our transactions by selecting the most valuable knowledge to transfer, by seeking devices to quicken the business, and by trying to save the labor-waste of the students. We have, besides, to add daily to our stock all the latest novelties. Despite all these pressing demands, we must keep the whole army of data in perfect order, under the command of general ideas and of natural laws. It is inevitable that the pressure on our energies should absorb most of their power so that we are habitually too busy to pause; and yet it is , I am sure, helpful to pause occasionally to consider, not the details, not the ways and means of our business, but its underlying principles.

May I regard this hour as such a pause, which we dedicate to an examination of the purposes of medical education and their best fulfillment? The function of a good medical school is to produce competent practitioners of medicine. I can not venture to call this an original idea of my own. Though it is a platitude to which all assent, it has its place here, in order to permit us to add that it is not the sole function of a good medical school, for only that medical school attains a high place, or even real importance, which adds on a large scale to medical knowledge and trains a steady succession of young men to become medical teachers. Only by the active pursuit of these high aims can the influence of a medical school inspire sound professional ideals in

---

[*] Commencement Address delivered before the Medical School of Washington University, St. Louis, May 27, 1909.

the minds of its students, practitioners to be. It appears, then, more accurate to put our platitude thus: The *chief* function of a medical school is to produce practitioners.

THE ESSENTIAL QUALITIES OF A PHYSICIAN

If we are to proceed intelligently, we must begin, it seems to me, with an inquiry as to what are the qualities which a physician should have, and the development or acquisition of which by students a medical school ought to render possible.

There is one quality the possession of which is the supreme need of the physician, without which he is as unfit and useless as a tone-deaf musician, or a color-blind painter. It is a quality with which every normal man is naturally endowed, just as every normal man is endowed with hearing and sight. But just as it is true that not every man can become a musician or an artist, so is it also true that for most men it is impossible to become good physicians, for the reason that they lack the one fundamental indispensable quality, that rare gift—a faculty of exact observation.

Accurate observation is by far the most difficult art which mankind has ever essayed. A nation may count on furnishing abundance of military talent—I begin with the lowest profession—plenty of politicians and statesmen, enough of competent lawyers; it may even hope to have gifted artists and authors; but it can scarcely expect to produce a single master of the art of observation in a century. It is important to realize this fact. Although the fact itself is beyond discussion, its significance is little heeded. The reasons for it are not far to seek. In most occupations a partial success is valuable; if a good result is gained it has a practical value. If a general wins a campaign, he is victorious; yet there probably was never a war which might not have been ended with less than the actual loss to the victors. A statesman whose constructive work benefits his country still does not produce perfect laws. Bismarck always dreaded the unforeseen consequences of his statesmanship. Lawyers have proved themselves useful, though litigation due to their imperfect work is incessant. A beautiful poem or picture may be a precious joy without reaching to the standard of absolute perfection. Scientific observation, on the contrary, aims for the absolute, and so far as it fails to establish the absolute truth it must be renewed, tried again and again, until every blemish is removed from it. Observation is accurate and good only when it attains absolute perfection. Religion sets before us an ideal of absolute moral perfection. All other ideals of men admit of limitations, allow of boundaries, save in our waking dreams and saving else only science, which claims from us the ideal of perfect observation, which alone can reveal the absolute truth.

In most professions merit is measured by a finite scale, but the scientific observer must strive toward the Absolute, which to our human powers seems infinitely remote. Because the ideal is so lofty very few come near it. In a century Germany produces one Helmholz, France one Pasteur, England one Darwin—an American peer of these three is yet to become known.

Observation is much more than seeing, hearing and feeling. Our sensory perceptions are but the beginning, and the simplest link in the chain of processes. Yet in my experience no young man, without prolonged and severe discipline, can be trusted to forge aright even this first link on the anvil of opportunity. To appreciate the real difficulties, we must pass behind the scenes and study the mental apparatus.

The faults of the observer are to be explained not so much by the working of his eye as by the failure to work of his brain. The organs of sense are, as the physiologists have taught us, imperfect, severely limited in their scope and ever ready to furnish us with defective sensations and illusions, but they work with astonishing accuracy as compared with the mind. In my long career as a teacher of medical science, I have had only two students whose eyes were not equal to good microscopic vision, but I have never had even a single student whose mind could perceive the retinal images obtained from microscopic preparations.

Successful scientific observation depends on three psychic factors: intelligence, concentrated attention, and judgment. Intelligence is necessary to guide the observer, who must before he begins have a clear understanding of the conditions by which the character of his observations is determined or modified. Above all, there must be an intelligent appreciation of what to look for, and an intelligent technical acquaintance with the methods to be employed. Only to a very limited extent, indeed, can the direct observation of natural conditions suffice. Herein, to my thinking, lies perhaps the most characteristic distinction between ordinary and scientific observation: the latter relies constantly on factors artificially introduced to expose objects too hidden or to record phenomena too remote or swift for observation. Indeed, science is based on the invention of methods of research, and the introduction of each new method is followed by an advance of knowledge. In order to realize this, we have merely to think what we owe to the methods of injection, of staining sections and bacteria, of making graphic records of the pulse and muscular contractions, of filtration and dialysis, of electric measurements, and so on through a list of immense extent. Without these numerous artificial methods our sciences would have remained rudimentary. Intelligence is, therefore, especially necessary to master methods, and no training in any natural science is more than a farce which does not give the student, first of all, a practical acquaintance with the methods used and of their advantages and their errors.

Concentrated attention we, of course, all know is indispensable, but, like other virtues, it is easier to commend than to practice. It is comfortable, after receiving a general impression, to pass on to something different with a fresh interest; but power is only for those who can sustain the closest attention for a long time, because otherwise details are overlooked, and the anticipated fact remains unnoticed. The ability to catch hold of the wholly unforeseen and significant phenomenon is the distinctive gift of a great mind. We are mentally blind to what we do not anticipate or at least know as a possible occurrence. The history of science is rich in illustrations to the point. One such curious illustration I may mention. For many years the red blood corpuscles of man and other mammals have been described as like biconcave discs in shape, but this form is to be observed really only as an artefact, and, as we now know, the corpuscles in life are cup-shaped, being hollow on one side and convex on the other. The truth has been known to us, however, only a very few years, because every one who examined the blood had a preconception of the corpuscular form, and was mentally blind to the evidence as to the real shape, of which any one can now easily satisfy himself, because his attention will be rightly directed. Innumerable instances could be compiled of scientific discoveries long missed because of failure to attend to some unexpectedly significant fact. It is by trained attention that we achieve accuracy and thoroughness; hence the first aim of the instruction in every scientific laboratory should be to impart to the student a habit of relentless attention and a high standard of exhaustive precision of observation. The quantity of information acquired is of minor importance.

Judgment is the highest quality. By attention and intelligence we may gather data, but judgment coins them into conclusions for the intellectual commerce of the world. Judgment, as here conceived, is much more than the judicial faculty, which is merely skill in balancing the pros and cons—a useful legal faculty, for the law courts deal with evidence mostly from average persons who are often biased by their interests, and in any case are ordinarily incapable of accurate observation. The law courts also follow a method, that of having opposing counsel on the two sides, which is absurd in science, though—be it confessed with sadness—this deplorable method is often mimicked in scientific debates. The scientific method is based on our belief that invariably the evidence must be wholly and exclusively on one side. If there is an apparent conflict, the duty of judgment is to find out, first, what part of the evidence is erroneous; second, what logical errors have occurred in the inductions drawn from the observations. As to the observed data, judgment must decide, first, whether they are to any extent erroneous; second, to what extent they are incomplete. For such a decision in any department of research to-day a thorough expert knowledge of the special subject is necessary, which must include not only intimate acquaintance with all previous work—a requirement too often shirked—but also intimacy with all the possible sources of error. Scientific judgment is a mental faculty which becomes efficient only after long experience and development. It is by illustrating in his own person the successful activity of this faculty that the professor of natural science exerts his most beneficent influence on his pupils.

Judgment renders its loftiest service when it deals with the logical inductions from the data. The first step logically—though often not psychologically—is the determination of the differences and of the resemblances among the data. Resemblances are far more difficult to recognize than dissimilarities and they are often as nonexistent to untrained minds. Then follow the proper reasoning processes which, if successful, carry us beyond the observations to the generalization, which makes part of the growth of science.

Now the nearer a practitioner of medicine comes to possessing the gift of observation, as just described, the better practitioner he will be; and, inasmuch as it is only in science that such ideals of observation are maintained, it is evident that a scientific training is indispensable to produce physicians psychologically fit. One still sometimes hears the distinction drawn between the "practical" and the "scientific" doctor; so far as I know, the most important difference between a "practical" doctor and the truly scientific is that the patients of the former are the more likely to die. Yet, of course, practical experience is of the utmost professional importance. Medicine is one application—only one of many—of biologic knowledge to practical needs, and the practical technic of the application must be mastered. There are useful practitioners of medicine whose utility is founded on their practical experience, but I had rather entrust myself to the care of one who had in addition to a practical technical mastery a mind educated to observe with scientific accuracy and reason with scientific precision. Those who extol the practical man and decry the scientific are of the sort who would rank plumbers above engineers.

St. Louis has had two physicians to whom I wish specially to allude, because they possessed the noble spirit of research to a pre-eminent degree. Their memories are held in honor wherever biologic science has a foothold. Both owe their well-earned reputations to their ability as scientific observers; Beaumont and Engelmann were practitioners, but their investigations demonstrate that they realized in their own persons the ideal we have before us. Their work has added an enduring luster to the fame of St. Louis. May they have many worthy successors!

The second quality, which both the medical student and the graduated physician must possess is, at least in my opinion, intellectual endurance. The medical mind must work not only well, but strenuously and continuously. The period of study in America is now actually from six to eight years, since four years has become the standard of the medical schools, and admission to them demands one or two years' work in the preliminary sciences, to all which a year or two in the hospital ought to be added. During every one of these years the student must work at high pressure, mastering one branch of science after another, learning the general principles, the technical methods and the practical applications of each, and gradually fitting himself for the art of practice. Having accomplished so much, he can not for an instant relax his acquisition of further knowledge, not merely from his own direct experience of diseased persons, but also by keeping abreast all his life with the progress of medicine. He must keep up not only with the improvements in medical treatment, but also with the advance of scientific knowledge. To do this perfectly has already become impossible, and the difficulty is constantly increasing. The older practitioner as he becomes busier, and his years render new modes of thought more difficult for him, must lag more and more behind the times and feel himself less and less well equipped than the on-coming young man. He is saved from discard only by his ripened judgment and his wisdom in dealing with patients. It is evident that intellectual endurance, a sustained mental power, an ever-active gift of apprehension, a ceaseless passion for knowing—call it what you will—is demanded of the members of the medical profession as of no other. Medicine is a profession which only men of exceptional ability should enter. Men of moderate gifts should seek other occupations. In the future, as medical knowledge becomes still more vast, high ability will be indispensable for those who try to master and apply it. No other profession is likely to equal it in difficulty, for the lawyers, engineers, architects, chemists and others have far less complicated problems than the physician; and their fields of knowledge are smaller. Moreover, specialization in the learned professions mentioned is far more feasible than in medicine, for every part of our bodies is related so intimately to every other part that no specialist can deal with his subject as an isolated field of practice. Not merely as in all scientific professions must a man keep up with the general progress of knowledge, but, since every organ is related physiologically and pathologically to every other, the medical specialist can not seclude himself in his chosen subject, but must preserve his active intercourse with all medical domains. The practitioner, no matter how much absorbed in work, must remain all his life a quick, diligent, alert, receptive learner. Never may he let himself feel a senescent apathy to new ideas. The ideal physician possesses a life-long intellectual endurance.

The psychologic traits desirable in members of the medical profession are many and complex. Even were I competent to review and discuss them all, such a disquisition would not suit this occasion, and it will suffice to keep our attention concentrated on a few fundamentals. Let us, therefore, content ourselves with adding loyalty as the third indispensable quality, for loyalty best expresses that quality of single-minded devotion, that trinity of faithfulness to occupation, to purpose and to person which makes us gratefully reverence the great physician. Loyalty is a natural gift, but, like all natural endowments of character, it may be cultivated, trained and strengthened. Our entering students rapidly classify themselves according to their loyalty to their immediate work. The best men already feel the gravity of their decision to become physicians; they appreciate the seriousness of their studies, and work faithfully each day with a prophetic instinct that each day's knowledge builds up the base for their future decisions. They are already filled with a sense of responsibility; and to nourish that sense, to sustain the loyalty of the learners should be the constant goal of the medical teachers' ambition. The student should be made to feel from the very start that his purpose in life must be to serve, and that devotion to his studies is his initiation into the life of perfect devotion to his patients.

REQUIREMENTS FOR A GOOD MEDICAL STUDENT

The man who purposes to study medicine should have in high degree three gifts, not one of which is common among mankind, yet all of which he must have. The three gifts are: the power of reliable observation, intellectual endurance, loyalty.

If the estimate we have made of the needed capacities of a physician be correct, it follows that a good medical school can exist only with good students. Coins of full value can not be made of impure metal. We must, therefore, start with the consideration of the means to select students to the exclusion not merely of the bad ones, but also of the mediocre. We must not attempt to mint doctors from merit basely alloyed. Examinations should have their main use, not as a means of admission, but as a means of exclusion, and the more men of low and middle rank that are excluded the better. One poor student damages a whole class. We should look forward to the exclusion of all men who fail to get high marks in the preliminary tests, so that there may be a reasonable probability that all who get in are capable of hard sustained mental work and of loyalty to their studies. The examinations ought, however, to accomplish more than this: they should afford evidence that the candidate has a natural power of observation, and that the power has already received some scientific discipline, and, finally, they ought to prove that the candidate has the preliminary knowledge of chemistry, physics and general biology without which the pursuit of the medical sciences is impossible. It is a welcome sign of progress that these entrance requirements are being rapidly adopted by the medical schools of the country, and there is, I am glad to perceive, a steady advance toward uniformity. In my opinion, such a preliminary training, with the appropriate sifting of the unfit, can be accomplished by two or three years of college work—and it is not and can not be accomplished by requiring an A.B. degree (or its equivalent) unless that degree represents adequate courses in chemistry, physics, biology, French and German. Under the prevalent elective system, a man may become a bachelor of arts and yet be not only undisciplined, but also very ignorant of natural science. I have had to do with many such men, and can only say that they are so inferior at the start that only the most brilliant of them can overcome the heavy handicap. Indeed, I can not affirm that even the brilliant men are able wholly to repair the evil, for in the rush of medical study they have no time to make up their deficiencies in the preliminary sciences. They enter as cripples and as cripples still they are likely to graduate from the medical school.

Although observation is the foundation of knowledge, and no human knowledge is built on any other foundation, men of intellectual power are by no means always interested in observation. There are mathematicians who can scarcely be said to feel interest in any observations. I often recall with amusement a distinguished mathematician whom I would not have trusted to make an original observation beyond a simple measurement, and yet who condescendingly explained to a company of biologists that their science must remain inaccurate until its results were mathematically formulated. The reply might have been made to him that no mathematical result can be accurately known until put in graphic form, so that it can be observed. The one half-truth is as good as the other. Our mathematical friend had still to learn that there is an accuracy in a complex visual image with which mathematics can not even distantly vie. We might construct a scale, with the anatomist at one end and the mathematician at the other; both alike depend on observation, but one seeks his accuracy chiefly in the renewal and extension of his personal observations—he loves first-hand knowledge; the other seeks his accuracy in the logical evolution of quantitative relations, and cares but little for the simple observations on which his mathematics depends. Between these two extremes we must range those minds which enjoy and seek both observational and logical satisfaction, and who are often experimenters. Among experimenters there is a wide range in the degree of relative interest—on the one hand, in what can be directly observed, and, on the other, in the logical work following the experiment. Only those in whom the love of observation is predominant are likely to succeed as physicians. For the pure experimenter there is plenty of room in medical science, but he can hardly find his right opportunity in medical practice.

The natural observer differs both from those who, like the humanitarians, are satisfied by second-hand knowledge, and from those who prefer experimental work, by his insatiable craving for seeing, and, to a less extent, for hearing and feeling. His inborn need is to have direct contact with the phenomena. Nothing short of the personal acquaintance with the phenomena satisfies him. Now those students who while in college elect the humanitarian studies, and neglect the natural sciences, are extremely unlikely to have the observing faculty. If they are required to study chemistry, physics and biology before they get to medical work they will be tried out, and those who have not the observer's gift, will learn their limitations in time to avoid becoming medical impedimenta.

THE STANDARDS FOR THE MEDICAL SCHOOL

Having obtained our students, we ask next: "What shall we teach them?" Really good answers to this question are given by the curricula of our better schools, which differ from one another only in detail, since in all the subjects are the same and the order in which they follow is essentially fixed.

Two comments on the present typical medical curriculum may be ventured: too much time is devoted to lectures, too little time to physiology. It is, if I be not mistaken, universally true that in American medical schools a large number of lectures are given which are mere repetitions of what is often better expounded in the text-book. It would, in my opinion, be wiser to devote many of the hours now used for lectures to practical work, restricting the lectures to general principles, the elucidation of complicated subjects, especially those which can be made clear by verbal explanation combined with drawings, models or experiments. Lectures at best can convey very little actual information, and their greatest usefulness is in exhibiting to the students the point of view, the intellectual attitude of the professor, who is not fit for his position unless his mental work is better than that of any of his students. The outlook in America is full of encouragement. Nowhere else in the world has laboratory instruction advanced as far and well as in this country. Germany must look to her laurels, for the whole university tradition there exalts the lecture. The system is strongly entrenched, for the professors depend on lecture fees. The future of scientific education depends on laboratories, and unless European universities imitate the American laboratory standards the stream of students from Europe to the United States will soon be greater than that of a generation ago from our country to Germany.

As regards physiology, have we not to deplore the fact that very few physicians think physiologically? It is only too true that if a practitioner is asked for a physiologic explanation, his answer is usually so lame that it can scarcely be said to go. Ask an oculist why the tears run on a cold day: or a clinician the cause of pain from indigestion, or how opium works, or what is the physiologic basis of shock; ask a gynecologist why birth occurs; ask a general practitioner the cause of senescence; or ask a surgeon how the after-effects of ether are caused—and the answer is likely to be by no means in physiologic terms, by no means an analysis of functions, but rather an empirical statement; and a physiologist listening might well feel himself transported to the middle ages. The body is a functioning machine, and when it does not work properly it ought not to be tinkered by empiricists working by rules, but examined and repaired by physicians, whose chief claim to confidence is that they are expert physiologists, whose knowledge of the bodily functions guides their practice. I deem the opinion sound which regards physiology as the central discipline of medicine, and maintains that a generous development of clinical physiology is the improvement needed above all others in our medical curriculum. We are all agreed as to the importance of anatomy in medical education—it can hardly be exaggerated—nevertheless, we may feel tempted to say that physiology is even more important.

In regard, however, to material resources, our schools differ widely; and those which suffer from deficient laboratories must either make up their deficiencies or go under, drowned in the flood of the progress of the others. We have in America to-day a number of laboratories at various medical schools which are serving as present standards. All the best teaching in the medical sciences is laboratory teaching. Each one of the sciences must have a large building and expensively equipped. The building must afford a separate work place for every individual student, rooms for the staff, rooms for advanced students and research; a lecture hall, library, and other necessary conveniences. These are merely minimum requirements, and mean that the cost of the plant for a respectable medical school is not to be reckoned by thousands, but by millions of dollars. There is no choice. Those responsible for the financial management may be staggered by the demands of their medical faculty; they may be able to meet the demands only partially for the time being, but in a comparatively few years from now only those medical schools will be found surviving which have met these demands. With time, too, the demands are sure to become more insistent and more numerous. Never have the financial responsibilities been so great, but, I repeat, there is no choice. The laboratory education is our one sure foundation. It is indispensable that it be amply provided for; if that can not be, the failure ought to be acknowledged and the school closed.

It is in the laboratories—and only in them—that the power of observation can be disciplined and developed, and only in them that the students can acquire genuine knowledge. In speaking thus, we class the hospital with the laboratory. It is my belief, strongly held, that a *laboratory is an efficient influence only when it is a* place where original research goes on actively. While it is true that the informational purpose guides the daily labor, and that it is indispensable that the student make by observation personal acquaintance with as many phenomena as practicable, yet it remains also true that the student should find in the laboratory an ideal standard of work—and the only possible high ideal is that of original investigation. It is relatively easy, under the guidance of an experienced instructor, with materials carefully prepared beforehand, to confirm by actual observation the statements of the text-book.

No doubt one exclusively so trained can become a useful mediocrity among practitioners; no doubt, even, that gifted men so trained will forge ahead despite the training; yet certainly a better education is secured when the students acquire appreciation of productive scholarship, and feel themselves so near it that it is an actual and living interest to them. Old discoveries do not stir much. We read calmly that some fact, which we find stated in all the text-books as familiar to everybody, was discovered fifty or forty or two hundred years ago by a man whose name awakens no significant associations. Utterly different is the effect on the student's mind when he learns that his instructor has made a successful research and has new discoveries to report. It is inspiring to him to know the discoverer. He feels himself a witness of the work of creation, and unconsciously his belief in the possibility and value of original work becomes a living influential conviction; and he rises at once to a higher intellectual plane. He advances on his way toward becoming a man of culture —a title which to-day only those can claim who have learned to revere productive scholarship.

Let us never forget that in contemporary education the moribund ideal is slavery to books; the nascent ideal, mastery of facts!

The consideration of our needs forces on us the conclusion that medical schools not only ought to be, but must be centers of research in order to succeed. To this end each school should be closely allied with the postgraduate department of its university, and the various medical sciences should be on a par in academic standing with the other natural sciences. Scientific students not intending to become physicians should be encouraged to enter the medical laboratories, and the highest university degrees should be as open to students of anatomy, pathology, bacteriology, physiology, etc., as to students of zoology, chemistry, or physics. If this policy be adopted with zeal, the reaction on the medical school will be wholesome, the effect on the university at large, uplifting.

THE SELECTION OF THE FACULTY

We have passed in review important aspects of the problem of maintaining a good medical school, but the most important factor of all, on which the successful solution of the problem chiefly depends, we have not yet mentioned; it is the corps of professors. Is it reckless to assert that no school has ever secured a sufficient number of sufficiently good professors? Perhaps no school ever will. As President Remsen has said, keenly and justly, the supply of good professors is always short. One great professor may leaven a whole faculty, but the need is for a great professor at the head of the five principal divisions: anatomy, physiology, pathology, medicine and surgery, and for first-class men at the head of the principal specialties. The majority of American medical schools certainly are without such corps of leaders.

The prevalent constitution of the medical faculties is due to various causes. First may be mentioned the survival of professors from an early epoch with lower standards; professors of anatomy who are not professional anatomists; of pathology who are busy practitioners; of clinical medicine, without knowledge of modern pathology. This difficulty cures itself. A second cause is the custom of promoting local men, who are rewarded with professorships for their faithfulness rather than for their ability. Every such promotion prevents the appointment of an abler man from outside. A third cause, and the most potent of all, is the American system of appointment by the president and trustees of the university, which often amounts to appointment by the president alone.

The administration of our colleges and universities has become more or less autocratic. The university president has great power, which we are accustomed to see liberally employed, on the whole, to the immense advantage of the university cause. President Gilman's service to higher education has our fullest admiration, and there are other presidents still living who are great leaders and whom we delight to honor. We can not regret this phase of our development, though there are many now who hope and believe that it is only a phase, and who welcome the unmistakable signs of the transformation of the office, by which the university president of the future will be more a business administrator and less a minister of education. The president is likely to long remain a valuable—an almost indispensable—factor in our university life; but, in my opinion, is not likely to retain any such control over appointments as he at present exercises. This control depends on the custom of having appointments made by the board of trustees, which is typically composed of business and professional men who are qualified to advise about the management of funds, the conservation of resources, and the distribution of income. The trustees ought, however, to admit frankly to themselves that their chief usefulness is, first, to increase the resources of the university; second, to determine the broad questions of general policy so as to secure a symmetrical growth of the institution. It is inevitable that the large majority of them should be inexpert in education, inadequate in their notions of scholarship, and ignorant of the needs, methods, and possibilities of most—if not all—kinds of original research. Such a board at its best can not by any possibility be a very successful piece of machinery for the selection of professors, because the members can not form a valuable judgment of their own concerning the only indispensable qualification of a candidate for a professorship—his ability to do original research of a high order. They forget too readily and too often that it is a disgrace to a university to appoint a man as professor chiefly because he is a "good teacher"—such a man may be a good school teacher, but only investigators can give university instruction.

In securing a faculty, the president and trustees must be guided by advice, and they undoubtedly are so guided to a very large extent at the present time. But the advice is too often gathered more or less fortuitously, and not by any definite custom or fixed principle. For our future welfare it is important to plan for obtaining the best advice, or, in other words, to make sure of good nominations being systematically presented. Accordingly, I look forward to seeing in the near future the task of nominating candidates for professorships and other teaching positions assigned to the university faculties.

It goes without saying that a university teacher must be by character and manners fitted to join a society of scholars and to come into intimate contact with young men and women. We can not, however, make every respectable gentleman a professor; but we must be sure that he has a sound, powerful, creative intellect, of which the only satisfactory proof is original research of a high order. In comparison with the possession of this intellectual gift, all other endowments are subsidiary. Professors may vary much in their ability to lecture, their availability for administrative work, in their adaptation to social life, in their capacity for business, in the quality of their minds; but all good professors are necessarily alike in the possession of creative mental power.

The selection of candidates for professorships must, then, be made by persons who can form expert judgment on the original investigations of the possible candidates. In universities, qualified judges are found in the faculties—and usually only in the faculties. To the faculty, then, ought to be given the exclusive right of nomination, leaving to the trustees only the right of confirmation; partly as a check against possible occasional errors of judgment by the faculty, partly as a financial safeguard against expense not warranted by the actual resources. This implies a radical reform in our universities; but until the time comes when teaching appointments can be initiated only by faculty action there will continue to be an unnecessarily large proportion of more or less incompetent professors.

Let us summarize the opinions expressed: A good medical school produces good physicians. The medical profession is a very difficult one, and to meet its requirements exceptional men must receive a splendid special training. Therefore, a good medical school will accept only such students as have been selected by severe tests with high standards; it will maintain lofty ideals of knowledge, of observation, of judgment, of original thought and of loyalty. It will uphold these ideals not only by striving to furnish every important material facility in laboratory and hospital, but also by engaging able instructors. The good medical school may become great which adopts as its motto: Great professors make a great school. Let this be your device, for the greater in ideals and achievement your school becomes, the more you will help and inspire all the other medical schools in our country.

Harvard Medical School.

THE SCIENCE OF CLINICAL MEDICINE

WHAT IT OUGHT TO BE AND THE MEN TO UPHOLD IT *

S. J. MELTZER, M.D., LL.D.
NEW YORK

The honor of the presidency of a society goes with the privilege of discussing some of the aims of that society. Such a privilege becomes a duty on the occasion of its first birthday. We have to show the specificity of our objects to justify the addition of a new medical society to the many already in existence. As your first president and as one of the instigators of the movement which led to the formation of this association permit me to discuss some of the problems to the solution of which this association wishes and hopes to contribute.

CLINICAL MEDICINE AS A SCIENCE

In the first place, I wish to discuss the problem of clinical medicine as a science. In years gone by, medicine was a unit and its leaders tried to master all its aspects. With the development of scientific methods and the growth of knowledge a process of differentiation took place. Heavy branches grew out of the stem of medicine, broke off and obtained an independent existence. Anatomy with all its dependencies broke away early, then followed physiology, pathologic anatomy, pharmacology and physiologic chemistry. Bacteriology tore off the branches of etiology and established itself as an independent growth. All these offsprings of medicine are now well established as pure sciences; they still closely affiliate with the mother-stem and are often designated as the sciences of medicine. That what is left of the old stem is clinical medicine. What is the character of this residuum? It is generally designated as the practice of medicine. I am not aware that any one has had the courage to call it a pure science. Those who do not like to call it an art say that it is an applied science. According to this view, the relation of clinical medicine to the sciences of medicine is that of technology to science in general. I am afraid that this conception of clinical medicine is widespread among those who are in the practice as well as among those who are in the sciences of medicine.

However this may be, I feel sure that such a view is logically erroneous and practically harmful. I wish to plead for an extension of the process of differentiation also to clinical medicine. I am of the opinion that clinical medicine as it exists now is made up of two constituents: one part has all the elements of a pure science and ought to be coordinate to the other pure sciences of medicine, and the other part is the real practice of medicine, an applied science which has many elements of an art. At present both parts are so closely interwoven that they present the appearance of a natural unit the splitting of which into two parts might appear to some as an impossible and undesirable process. I shall call to mind, however, that medicine made the same impression of an indivisible unit in the days when pathologic anatomy, physiology, etc., were inseparable constituents. To-day nobody doubts the necessity of an independent existence for the last-named constituents of former medicine. A considerable degree of separation of the science of clinical medicine from its practice is more desirable than even the separation of the coordinate sciences, because the requirements of sciences and practice are in a certain sense mutually antagonistic to one another and the simultaneous cultivation of both branches with equal attention is detrimental to the progress of either of them.

There is a fundamental difference between science and its correlated practice in any sphere of human activity. Science wishes to attain truthful knowledge of the subject it investigates. It attains this end in the safest way when it is least side-tracked by any extraneous motives. The motive of utility obscures its vision, and haste retards its progress. Practice, on the other hand, avails itself of acquired knowledge for the purpose of attaining a certain useful end. The more reliable that knowledge is which it has to employ, the more safely will it attain that end. But the use of any part of that knowledge which is indifferent to the attainment of the useful end hampers the practical progress. In other words, practice gains its ends best the purer the quality and the smaller the quantity of the science which it has to use. Permit me to say that my advocacy of the separation of a clinical science from its practice is not actuated by any disregard for the practice of medicine. On the contrary, I entertain now and have always entertained a strong conviction that the efficiency of practice should be the supreme object in medicine. At the same time I feel sure that the efficiency of that practice will be best attained when the search for the knowledge which the practice has to use should be carried on in the same manner and by the same methods as are employed in the search for knowledge in other branches of intellectual activity. In other words, clinical research should be raised to a department of a clinical science and be theoretically and practically separated to a considerable degree from the mere practical interests, that is, separated so far as the various and variable conditions permit. It will be the practice not less than the science of medicine which will benefit by such a separation.

Now let us see what the domain of clinical medicine is and whether it contains problems which can be treated by the methods employed in pure science. The sciences of normal anatomy and physiology teach us the structures and functions of the normal body; pathologic anatomy tells us of the anatomic changes found in a body dead from one disease or another. To clinical medicine is left the study of the phenomena and their sequence as they occur in a living body during the entire course of a disease. It has to interpret these phenomena by known physiologic laws, to identify them with similar phenomena experimentally produced in animals and it has to correlate the phenomena observed in the course of a certain disease during life with the anatomic changes found at the postmortem examinations in case the disease has a fatal termination. It is also one

---

* Presidential address at the first meeting of the Association for the Advancement of Clinical Research, May 10, 1909, Washington, D. C.

of the tasks of clinical medicine to study the influence on the onset and course of phenomena of diseases which certain means and remedies may exert whose physiologic actions are well established. In other words, the domain of clinical research comprises the study of the natural history of diseases, their physiology and their pharmacology. Can there be any doubt that these studies constitute legitimate objects of a pure science? Objections may be raised, and will be raised in certain quarters, against the admission of the clinical science to the sacred inner circle of pure sciences on account of the impossibility in clinical medicine to verify the conclusions by the experimental methods. Assuming that this is an unassailable fact, what of it? Are the problems of biology, a science which enjoys an unassailable position in the councils of pure sciences, all or many of them provable by experiment? Or are the sciences of paleontology or geology amenable to an experimental proof? Yet nobody questions the scientific right of these branches of human knowledge. Furthermore, admitting that clinical research must necessarily remain less precise and its results less convincing than that, for instance, of physiology. But, then, physiology itself is again a great deal less precise than physics and chemistry and is certainly less irrefutable than anatomy. Does this throw a doubt on the claim of physiology to be a pure science?

As to the impossibility of verifying certain conclusions regarding human diseases by human experimentation, there is still this much to say. Each disease is an experiment which Nature makes on the organism. The very large number and the great variations of these experiments of Nature offer favorable opportunities for testing the theories made regarding the nature of these spontaneous experiments. Furthermore, clinical research should, indeed, be coupled with animal experimentation; any new point of view gained by observation in clinical medicine which can not be verified on human beings should be tested by experiments on animals. By such a procedure not only clinical medicine, but also physiology may learn a good deal, for which the following facts from the recent history of medicine are classical illustrations. The recognition of myxedema as a special type of disease led to the understanding of the function of the thyroid glands, and the observation of the coincidence of pathologic processes of the pancreas with diabetes led to the discovery by clinical investigators of the glycolytic function of the pancreas. Finally, it should be borne in mind that there are lines of experimentation which may be carried out even on the sick human being without any detriment to him and which can be conducted with profit only by trained scientific observers, for instance some studies in pharmacology or in metabolism.

Among the tasks of clinical medicine there is one which is on the borderland between the science and practice of medicine, being perhaps of greater importance to the latter than to the former. It is the search for simple or complicated means by which established units of diseases may be recognized safely and perhaps also easily. In one word, it is diagnosis. Since this activity is not carried on with a purpose of adding knowledge, it would appear that it belongs rather to the department of the practice of medicine. Such facts can be established only by means of careful critical observations and it will be more to the purpose when at least the development of the principles of diagnosis should remain in the hands trained in careful methods of research.

After showing that there is a definite field for a science of clinical medicine the next question is who should be the men to carry on the research in this field, what should be their qualifications? In the first place, they must have a training fitting them to carry out investigations in conformity with the requirements existing in all pure sciences. They must not only be informed and trained in the other sciences of medicine, but must have carried on various investigations in one or more of these pure sciences, so as to become familiar with careful scientific methods and imbued with a scientific spirit. They will thus learn best how to shape a problem so as to make it amenable to a solution; how to marshall the consecutive steps of an investigation so as to bring out the reply to the question in hand. They will learn to avoid bias in the search, to apply criticism to the findings; they will learn not to trust only few facts, not to rejoice prematurely over findings and not to be disheartened by failures. They will thus acquire the habits and the tastes of the investigator, the scientist, which may then stick to them for life.

However, after all these preparations they must select clinical research as the main field of their scientific activity. Clinical science will not thrive through chance investigations by friendly neighbors from the adjoining practical and scientific domains. Such volunteer service which for the present is keeping up the cultivation of the unacclaimed region is most certainly very welcome. But the acclamation, cultivation and maintenance of a field of pure science of clinical medicine can not be accomplished by chance services from volunteers; for such a purpose we need the service of a standing army of regulars. The investigator in clinical science must devote the best part of his time and intellectual energies to the cultivation and elevation of this field just as the the physiologist does in his domain—or at least as he ought to do. For the sake of elucidation let us compare the relations of a science of clinical medicine to its practice with the relations of science to technology in any part of physics or chemistry. Let us take electricity as an instance. In the electrical industry there is a large corps of electrical engineers who are bright, inventive and on the alert to make practical use of any newly discovered principle in general. Some practical engineers manage to make valuable contributions to the theoretical knowledge of their branch. Nevertheless the science of electricity is in the hands of pure scientists who are setting the pace of progress in the correlated practical branch. It is the discovery in pure science which makes great inventions possible. It was, for instance, the purely scientific demonstration by Hertz of the existence of electric waves that gave the impetus to and made the invention of wireless telegraphy possible. The following is a quotation from the presidential address of Professor Nichols before the Association for Advancement of Science[1]: "Communities having the most thorough fundamental knowledge of pure science will show the greatest output of really practical inventions." This is surely true also for medicine. And let me say to you that the Hertz's, the Roentgens, the Bunsens, the Emil Fischers, and a host of others, who are the real creators of knowledge and invention, are satisfied to live on comparatively small salaries, while it is within their easy reach to make twenty times the amount of their salaries as consultants, if they would be willing to give up a part of their time which they devote to investigations in pure science. Now, the leaders in practical engineering in electricity surely compare favorably with the leaders in the practice of medicine with regard to the completeness of their knowledge in the respective spheres. While thus the search for knowledge in electricity is carried on by men devoting themselves to pure science, the search for knowledge in clinical medicine is left in the hands of men who devote most of their time and energies to their practice and to the golden fruit it bears. Under such circumstances, how shall we expect to find the progress in science and practice of medicine keeping abreast with the striking progress to be met with in other branches of science and practice?

---

[1] Science, Jan. 1, 1909, p. 5.

A few years ago I tried to fix the responsibility for the shortcoming of internal medicine in physiology, because this science is keeping aloof from medicine and its problems.[2] Anatomy, which gave its undivided attention to the human structures, prepared an excellent basis for a successful surgery, the problems of which are essentially mechanical in character. The problems of clinical medicine are essentially of a functional character, and the enlightenment which it requires must come from physiology. This science, however, developed a tendency to keep at a distance from medicine on account of the inexactness of the latter. There is an improvement to be noted in this regard; there is a growing tendency in physiology nowadays to pay greater attention to medical problems. However, even if physiology and other related medical sciences would devote all their time and energy to the study of purely medical problems, it would not bring about a radical solution of our perplexing problem. Neither will this be accomplished by the creation of chairs for experimental medicine. The regeneration or rather creation of a science of clinical medicine must come from the innermost of medicine itself. It is true, as stated before, that the men who are to tackle these problems must have a thorough training in the sciences allied to medicine, but the center of their activities must be within clinical medicine itself. They must have a bringing up within medicine, their minds must have been filled up with thinking, worrying, brooding over practical and theoretical problems of clinical medicine.

Let me recapitulate. There is a necessity for a differentiation of clinical medicine into a science and a practice. The clinical science has well-defined objects and is a most important department. It must be managed by a set of men specially trained for and almost exclusively devoted to that task. Without the development of such a department of clinical science the efficiency of the practice of internal medicine will lag behind, no matter how progressive the allied sciences of medicine are and how great their efforts to be useful to medicine may be.

THE CONDITIONS AS THEY ACTUALLY EXIST

In conjunction with the foregoing considerations let me glance at the conditions of clinical medicine as they actually exist here and abroad. I may state that neither abroad nor here do we find a separate class of investigators confining their activity solely to the domain of the science of clinical medicine. Everywhere science and practice of clinical medicine go hand in hand. We may, however, admit at the outset that there is an enormous difference in the status of medical research between abroad and here. Let us take the development and the present status of clinical medicine of the German-speaking countries as an illustration of the conditions abroad. We shall notice that there the mother stem of medicine managed to retain a scientific aspect despite all processes of differentiation.

When for the first time pathologic anatomy broke away completely from medicine and was taught by Rokitansky at the University of Vienna as an independent branch of medical science, we find that at the same time and at the same place the celebrated Skoda was teaching the remaining trunk of clinical medicine as a natural science, constructing the methods of auscultation and percussion on a sound basis and establishing a firm connection between the *intravitam* diagnosis and the postmortem findings. The purely anatomic tendencies of that celebrated school of medicine which unfortunately gave birth to nihilism in medicine, was soon curbed by the appearance of Virchow on the medical scene in Berlin. While also working for the establishment of pathologic anatomy, gross and histologic, as an independent natural science, he manifested throughout his long life a deep interest in the development of clinical medicine on sound lines. At the very beginning of his brilliant career we find him stating (in the prospectus to the first volume of his *Archiv*) that practice of medicine should be an applied science and the ideal of the science should be a complete pathologic physiology. The great clinical contemporaries of Virchow strove for a similar ideal. Frerichs introduced chemistry and Ludwig Traube the methods of experimental physiology into the domain of clinical medicine. I shall not dwell here further on historical details. I shall only say that clinical medicine in Germany remained true to this ideal throughout all these years of marvelous growth of medicine. The exponents of clinical medicine in Germany are the flag bearers of pathologic physiology. The contemporary clinicians master the immense knowledge and manual skill which contemporary clinical medicine demands of its disciples, and nearly all of them are themselves diligently adding new facts to the store of medical science. I do not need to tell you the particulars. Some of you know from personal experience such master clinicians like Müller, Krehl, Kraus, Minkowsky, and a good many others like them. However, the standard of medicine is kept high not only by the heads of university clinics; the various members of their staffs, heads of hospitals and their staffs and a host of volunteer workers are continually digging for new fruit in the soil of clinical medicine. The medical literature is full of original, first-rate work in the science of clinical as well as of experimental medicine contributed by men whose main abode is clinical medicine.

Now there is in Germany no special chair for the science of clinical or even experimental medicine. All these contributors to medical science are in a sense simply medical practitioners. What is the secret of their scientific success? It is simply this: to these men science is the first and practice the second object of their life. To most of the leaders of medicine in Germany the tasks of gaining and diffusing knowledge receives their first attention and the consultation practice comes in last. Again, these very leaders before they have acquired their commanding positions spent many years of their life in preparing themselves for it; in training in scientic methods, in acquiring knowledge in the allied sciences and in the science and practice of clinical medicine, living meanwhile on small incomes, having no private practice at all or having a practice too small to interfere with their life ambition. You can not lead such a life unless you are possessed by idealism and a scientific spirit. That is the key to their success. And when these men become teachers, they can not fail to impart this ideal spirit to their students. That is the way they themselves received it. But they received it also in the institutions of their early education, where sport and habits of millionaires' sons are not the factors which form the character of the youth. They received it from the people among whom they grew up, among whom the worth of the individual is not measured exclusively by a gold standard. They received it from the care and encouragement of the government which, no matter what its political ideals may be, never loses sight of the fact that the cultivation of science is one of the greatest assets of a people. They received it in the traditions of medicine of their country; even before the new era when medicine was all in a cloud of so-called natural philosophy, only the substance of medicine was all wrong, its spirit was all right.

---

[2] Congress of Science and Art, 1904, v, 395; chairman's address.

That is the situation abroad. Now let us look at the development and the present status of clinical medicine in this country. At a glance one observes with amazement that nearly all the factors which favored the development of a scientfiic spirit in Germany are absent. However, I shall not try to enumerate all the shortcomings with which the development of medicine in this country had and still has to contend. There is no educational advantage in doing it and you are all familiar with the situation. On the contrary, I take pleasure in pointing out the encouraging fact that, despite all the difficulties, medicine in this country gradually rose to a commanding position in many respects. It is an instructive and stimulating fact that the progress of medicine in this country was carried on through the efforts of a few high-minded men or groups of men who at various times transplanted the spirit prevailing abroad into this country. I shall, of course, not attempt to enter into the particulars of the history of this progress. I wish to refer briefly, however, to a few phases in this history. In the first important phase, clinical medicine in America received an elevating impulse through the activities of a group of medical men who continued their studies in France, where they came especially under the influence of the famous clinician Louis. Statistical methods of observation of diseases and diagnosis by auscultation and percussion became, then, the chief characteristics of internal medicine in this country. During the second period, young American physicians pursued their postgraduate studies in Austria and Germany. They brought home a knowledge of gross and minute pathologic anatomy and an aptitude for the use of the microscope. Pathologic societies were started and the teachers of medicine began to give separate lectures on pathologic anatomy and to instruct in the use of the microscope as a clinical aid. The studies and teaching of these new subjects gave at that time a scientific flavor to clinical medicine. The last period covers about the three last decades with the contradictory results of which we are confronted to-day. Again, medical men went abroad for postgraduate studies and perhaps in larger numbers than ever. But what this high class of young medical men studied there now was no longer in the direct interest of clinical medicine; they trained themselves in the intricacies of the sciences of medicine. The results of the studies of this period were again of great benefit to medicine in this country; in fact, they were of greater benefit than ever. In a comparatively short period the special sciences of medicine, thanks to the activity of a brilliant group of men, have gained a strong foothold in this country; special chairs and laboratories were created in many schools of medicine for pathology, physiology, bacteriology, pharmacology and physiologic chemistry. The work which is being accomplished now in these laboratories compares favorably with the work done in the countries with older scientific traditions and much more favorable surroundings. However, by this very departure clinical medicine itself suffered a visible retardation in the development of its own department. I discuss this phase not with pleasure, but the truth must be said. To my mind it is a fact that the leading clinicians of this generation do not compare favorably with their predecessors in this country, not to speak of a comparison with the leaders of clinical medicine in other countries. One of the reasons for the retardation in the progress is the loss to clinical medicine of the brainy men who now devote their energies to the pure sciences of medicine. Another reason may be found in the fact that by giving up pathologic anatomy and microscopy to special departments clinical medicine lost that part which has given it formerly its scientific character. An evident drawback to the progress of internal medicine in this country is the fact that its teaching at the present time is mostly still in the hands of men who received their medical training nearly exclusively in this country and at a time when pathologic anatomy was the exclusive basis and auscultation and percussion practically the exclusive methods of diagnosis. But in the last twenty-five years internal medicine changed its aspect greatly. The men who want to teach the medicine of to-day must have an education and training radically different from those which were customary and sufficient in former years.

However, the greatest evil of them all is the deplorable fact that in most instances internal medicine is taught in this country by very busy consultants who can give only a small fraction of their time and mental energy to this one of the side issues of their busy lives. Teaching medicine and furthering its science is a very serious business which ought to be carried on by men who are ready to devote all or most of their time to it.

Here are problems for you to solve. The progress of clinical medicine in this country has to be accelerated again. We might reach the level which we have seen to exist abroad. But we ought to strive to get still higher; in this field lack of modesty is a stimulating virtue. Look at the allied sciences of medicine, the level of which they have reached in a comparatively short time without any tradition and only through the activity of a small group of high-minded men. The progress of medicine in this country was always carried on by the few and not by the masses. Clinical medicine must reclaim some of the brainy young men who were enticed by the sciences of medicine. You represent a new generation. You have had an education and a training in modern medicine and the allied sciences. You have a training in investigation, the constitution requires it of you. The constitution which you have adopted shows your spirit. Among its objects is "the cultivation of clinical research by the methods of the natural sciences and the diffusion of a scientific spirit among its members." But you will accomplish more; the constitution imposes on you the obligation to be active in the diffusion of the principles of the society particularly among the students who come under your charge. I would recall this obligation to the minds of the members who were called within this year to chairs of medicine at influential places. The constitution does not keep you down exclusively to science, but let me tell you: beware of practice. It is a bewitching graveyard in which many a brain has been buried alive with no other compensation than a gilded tombstone.

One last word. The men whom you now see sitting on the bank left behind while the boat of progress swiftly glides away with fresh winds and under fresh sails were themselves in their youth passengers of similar boats and cut faces at others who were left behind. Be generous to them, but do not repeat their mistakes. The secret is: never leave the boat.

THE NEED, METHODS AND VALUE OF MEDICAL COLLEGE INSPECTION*

N. P. COLWELL, M.D.
Secretary of the Council on Medical Education, of the American Medical Association
CHICAGO

That we have in this country no national body having legal power to charter and control educational institutions is generally understood. Under our system of government this control, along with the licensing of physicians, belongs to the police powers of the various states. In the majority of foreign countries, however, there are national boards or committees which charter all schools, including medical, and which insist on definite standards being maintained.

This country is still comparatively young and in some respects has not attained full growth. Our educational institutions have been allowed to shift for themselves and, of course, much confusion of standards has resulted. The past eight or ten years, however, has seen a gradual development toward system and in the last few years particularly rapid progress has been made. At the present time only three or four states regulate the chartering of institutions, while in the majority of states any body of men can secure articles of incorporation for a college or school by paying the required fee, no question being raised regarding the ability of the incorporators to furnish education.

As might be expected, we have, taking the country as a whole, a large number of educational institutions—including medical colleges—with a great variety of methods and standards. We find some high schools and academies attempting to teach college subjects to students from the elementary grades and, worse still, we also have so-called colleges and universities teaching high school subjects and granting baccalaureate degrees on that basis.

VARIETY OF "MEDICAL COLLEGES"

When we come to the institutions professing to teach medicine in whole or in part, we find even greater confusion. From the various healing cults which have no use for the fundamental principles of medical science up to the thoroughly equipped, high-grade university medical schools—and all must be included in any complete investigation of medical education—this country has more medical schools than all the rest of the world combined and, on the whole, lower standards than are to be found in any other country.

The medical cults referred to have practically no standards or, at best, enforce only a common school education for admission and give a two or three year course, after which they turn out "doctors" of this, that, or the other—it does not matter to the average layman who doesn't know the difference. But even among the schools usually included in the term "medical colleges" there is a most amazing variety of standards. There are several, the entire equipment of which consists of a blackboard, a table and some chairs. There are some which merely drill their students in answering questions asked at state board examinations, having no use for laboratories and clinics. Meanwhile the graduates of these schools usually succeed in passing the state license examinations. There are colleges which grant the degree after a course given in the 2½ or 3 hours at night for four years of 30 or 40 weeks each, which, to equal the actual time spent by students in our day schools, would require from 12 to 14 years. There are still colleges at which ungraded courses of lectures are given year after year to all classes alike. There are legally chartered medical colleges located in towns so small as to make clinical material seriously limited or entirely lacking. There are several at which no clinical training in obstetrics is given and more at which no postmortems are seen by the students and where there is no opportunity to study gross pathologic specimens. On the other hand, there are numerous grades of institutions up to the small but increasing number of high grade medical colleges which are probably equal to any in the world.

I have given only a brief statement of the amazing variety of institutions professing to teach medical students and which are annually turning out armies of those who seek the privilege of practicing medicine. While many are thoroughly competent, there are, doubtless, many who are illiterate, untrained and decidedly incompetent. While they differ greatly in their educational qualifications and possibly in their "methods of treatment," those who, by whatever hook or crook, secure the right to practice will be alike in this respect: they will all be required to differentiate between health and disease, to determine the nature of diseases, deformities and injuries, and to stand between life and death in many of the cases to which they may be called.

IMPORTANCE OF STATE BOARDS

Under our form of government, the only legal barrier which stands between a sick and suffering humanity and this job-lot of would-be practitioners is the state licensing board. How important it is, therefore, that the state board be given full power, and that all obstacles be removed from its path. The splendid work that has been done by these boards, often in spite of many difficulties, is the most hopeful sign that this problem will, in time, be properly solved.

At the present time, however, too many obstacles are hindering the boards from obtaining the best results. There are now some 65 or more boards in the 50 states, only a few of which are given sufficient financial support to permit of the best work, and many are continually having to contend with the inconsistencies of legislatures, which, after adopting strong medical practice acts, containing fair educational standards, proceed to limit seriously the board's power by granting special legislation to this, that or the other medical sect, providing for special standards or special boards. It has been stated by attorneys that, if fairly tested in the courts, such special legislation would probably be declared unconstitutional. The solution of the sectarian problem seems logically to be the adoption of an educational standard with which all medical schools professing to train those who are to practice medicine and differentiate between health and disease must comply. If it can be ascertained that the medical school is up to that standard and the graduate passes the examination, then grant a physician's license and let the holder practice by whatever method his educated common sense may dictate.

---

* Read before the Nineteenth Annual Convention of the National Confederation of State Medical Examining and Licensing Boards, Atlantic City, N. J., June 7, 1909.

INVESTIGATIONS OF MEDICAL COLLEGES NEEDED

Such an educational standard could not be drawn up without a complete knowledge of the conditions existing and nothing would more thoroughly reveal the need of an effective regulation of medical practice and thereby strengthen the power of state examining boards than a thorough investigation of medical education, including an actual inspection of every institution professing to teach medicine. This investigation should be national in its scope and should be free from any political, local or sectional bias. If thoroughly made it would be of much benefit in many ways. Low grade and fraudulent institutions would be exposed properly, while colleges which are honestly endeavoring to keep abreast of the increasing demands of medical education would be benefited. The necessity for the endowment of medical education could be emphasized and deserving schools pointed out. Such an investigation would also simplify the work of the State Examining Boards. It would reveal the schools which state boards would not care to recognize and, although some practice acts may require that the board itself make inspections before the withdrawal of recognition, such inspections would need to be made only of the colleges which were declared unsatisfactory by this investigation. From the standpoint of expense alone, each state board could scarcely be expected to examine every medical college in the country and fifty different inspections by as many different boards would be poor economy, would lead to much confusion and would be an unnecessary burden on the medical college.

I have purposely used the word "investigation," since to obtain accurate knowledge would require much more than is usually meant by an "inspection." Nevertheless the inspection is a very essential part of the investigation. In fact the inspection should be an investigation at first hand, on the premises, to find out whether the college really exists, what it has in the way of equipment and what it is doing. Without this actual inspection any investigation is far from complete, considering what is so generally known, that statements made in medical college announcements can not always be relied on. You all have doubtless heard it remarked that a statement not strictly true may be so often repeated that the narrator comes to believe it true. At any rate, at the inspections the investigator will sometimes hear statements which are not borne out by the facts. During the investigation, therefore, nothing should be taken for granted and leading questions should be avoided. Careful notes should be taken and as much corroboratory evidence should be secured as possible. These statements may seem harsh, but to learn the truth the methods outlined are in some instances quite necessary. If falsification in college announcements has been resorted to or if wrong or misleading statements are made during the inspection it is highly important that the investigator learn the actual facts. Colleges which are honest in their efforts and intentions always welcome investigations and doubtless prefer that such investigations be thorough. Each college is a problem in itself and the methods followed in the investigation will necessarily vary. The following, however, will give a rough outline of some of the points which should be systematically taken up in the inspection of all colleges:

METHODS OF INVESTIGATION

1. **The Character of the College.**—Inquiry should be made to learn whether it is a stock corporation or whether a department of a university; whether its finances are controlled by the faculty or by a separate board of trustees and, if a department of a university, what control the latter has of the finances and standards. If there are departments of pharmacy and dentistry it should be learned to what extent the students are taught together and the differences, if any, in the preliminary requirements.

2. **Finances.**—The income from students' fees, endowments or other sources should be learned, as well as the various items of expenditure. Financial statements should be studied if available. The number of students enrolled and the tuition fees should be noted.

3. **Faculty.**—The relation of the faculty members to the various chairs should be learned, and, when chairs are vacated for any reason, how successors are chosen. The number of salaried instructors should be learned, the amount of time devoted to teaching and the subjects handled by each. The qualifications of the faculty members is, of course, a matter of much importance.

4. **Entrance Requirements.**—The entrance records should be inspected and also the original credentials handed in by the students. Special note should be made of the institutions granting the credentials and from any source possible a knowledge of these institutions obtained in order that a proper valuation of the credentials can be made. If any outside party, such as a high-school principal or the county superintendent of schools, passes on the credentials or conducts the entrance examinations for the medical college, he should be interviewed and his methods learned.

5. **Advanced Standing.**—The methods of granting advanced standing from other institutions should be learned and note made of the medical schools from which credentials have been accepted.

6. **Length of Course.**—The dates of beginning and ending the sessions should be obtained and inquiry made regarding holidays, time allowed for matriculation and the requirements of attendance at classes.

7. **Character of the Curriculum.**—The lecture or class schedule actually in use by the college should be studied to learn whether the course is graded, to see what subjects are being taught and by what methods: lecture, laboratory or clinic. If clinics are mentioned it should be learned whether they are held at the college dispensary or at hospitals, and what hospitals.

8. **Buildings.**—The condition of the buildings as regards care and utility should be noted. Ample space for the accommodation of the classes and ample provision for light, heat and ventilation are of more importance than architectural beauty. General cleanliness is important since aseptic methods cannot well be taught in filthy buildings and laboratories.

9. **Laboratories.**—The number of laboratories, the subjects taught in each, the equipment and the evidences of recent active work are of much importance. This furnishes a fair idea as to whether or not the college is keeping up to date in its methods of teaching. Any

evidences of original research should be noted. The inspector should examine students' note-books, tracings or other evidence of students' work. The presence of an all-time, salaried instructor and the character of his work are usually indicated in the appearance of the laboratory and equipment. According to the subject taught in the laboratory, the following points should be noted:

(a) Anatomy.—The amount and character of the dissecting material should be noted and whether modern methods of embalming are used by which dissection is made more safe and pleasant than by the old methods. The use of cadavers for operative surgery and the use of frozen cross sections, or other prepared anatomic specimens, charts, or other modern adjuncts should be noted.

(b) Physiology.—In any laboratory which is at all equipped for teaching physiology the inspector will invariably see such apparatus as kymographs, levers, time-markers, electrical apparatus, etc. The presence of animals and frogs will be additional evidence of modern methods. Students' individual work, such as note-books, tracings, etc., will furnish a good idea of the work done.

(c) Chemistry.—Here cleanliness is an important consideration. The presence and character of the apparatus and reagent bottles will indicate whether the work is limited to general chemistry or whether organic and physiologic chemistry are also taught. Outlines of the courses taught should be studied if available.

(d) Histology and Embryology.—The supply and character of microscopes, microtomes, bottles of blocked specimens, or cut sections will usually be seen. Any additional apparatus such as stereopticons, charts, etc., should be noted. Evidences of active work by teacher or students are important. For embryology the same apparatus and in addition the presence of incubators, charts, models or other adjuncts should be noted.

(e) Bacteriology.—An ample supply of good oil-immersion microscopes is a necessity. Note should also be made of sterilizers, incubators, test tubes, prepared media (potato, gelatin, agar-agar, etc.) and cultures. Cleanliness in this laboratory is of particular importance for the sake of the student himself as well as for the reliability of his work. The presence or use of animals and the manner of caring for them should be noted.

(f) Pathology.—An ample supply of microscopes is necessary, unless those used in histology or bacteriology are easily accessible. The number of gross and microscopic material should be noted. If any postmortems are being done by a careful instructor, there will usually be evidences of it in a supply of preserved gross specimens in this laboratory or in the museum.

(g) Pharmacology, Materia Medica and Therapeutics.—Note should be made of laboratories for these subjects, particularly the first, and any available outlines of work should be studied.

(h) Clinical Laboratories.—Of great importance are the facilities for training students to make the various laboratory diagnostic tests of blood, urine, sputum, etc., and note should be made of any laboratories for the purpose and whether they are amply equipped with microscopes, reagents, stains, burettes, blood counting outfits, etc. Small laboratories for this purpose are sometimes found in hospitals, in which case it should be learned whether the students have regular work there or whether the work is all done by the internes.

(i) Other Laboratories.—Any advanced research, public health or other laboratories should be noted, but particular inquiry should be made as to the part such have in the training of medical students, since that is the chief function of the medical college.

10. Dispensary.—It should be noted whether a suite of rooms or a single room or merely the college office is used for dispensary purposes. The sanitary condition of these rooms, the equipment, and the evidences of active work are important. If possible the visit should be made during the regular dispensary hours that it may be seen how many patients are in attendance and what part the students have in the examination and care of these patients. The records of patients should be inspected and the average daily or weekly attendance noted.

11. Hospitals.—All hospitals at which the college claims to hold clinics should be visited and evidence obtained regarding the actual attendance of students. The average number of patients in the hospital and particularly the average number of free or ward cases which can be used for teaching purposes should be learned. The number of clinics per week held in each hospital should be noted and whether they appear on the lecture schedule or not. The amount and character of the work done by the students in the examination and treatment of patients is of particular importance, as well as the opportunity for training in the various departments of medicine, surgery, gynecology, obstetrics, pediatrics, etc.

12. Maternity Work.—Special inquiry should be made regarding the number of cases required of each senior student, the extent of the student's responsibility in the handling and care of each case, the number of cases obtained and where they are obtained. Maternity wards of hospitals should be visited and the actual number of patients noted.

12.—Library.—If the college has a medical library, note should be made of its accessibility to students and the arrangements for the students' comfort, the presence of a librarian, the number of modern and useful text and reference books and the number of useful medical periodicals. Only too often there will be found a lot of old, out-of-date volumes of no particular use to medical students. Of far more importance than the mere presence of a medical library are the evidences that it is used and useful in the training of medical students.

14. Museum.—It should be noted whether there is a good supply of modern useful anatomic, pathologic, surgical, obstetric or other specimens or whether the collection consists merely of old, useless curiosities; whether the specimens are labeled; whether an index is kept and, in connection with the pathologic specimens, whether the clinical histories are systematically filed for reference. In fact, the important point, as with the medical library, is the extent to which this museum is used in medical teaching.

15. Special Features.—Note should be made of any special features, such as freezing plants for preserving cadavers, animal houses or dog hospitals, and of any special apparatus, as reflectoscopes, Roentgen-ray outfits, charts, models, manikins, etc.

16. Supplementary Information.—Besides the information obtained directly through the inspection, other sources should be looked to for whatever will aid in forming an accurate idea of what the college is doing. The finished product, the graduates of the colleges, should be considered. The success or the failure of its graduates at state license examinations, their success and standing among practitioners and educators, the places they secure in hospitals, public health positions and elsewhere wherein they can show the training received while in the medical college—all these facts are of much importance.

OTHER FACTORS

This outline has not been given with any intention of indicating a complete equipment for any medical college, nor should there be any fixed requirement of equipment any more than there should be a hard and fast curriculum. After all has been seen and learned, much must be left to the judgment of the inspection committee. While the entire absence of equipment is serious, the mere fact that apparatus is present is of little consequence. There may be dissecting tables, but no anatomic material and other evidence may lead the inspectors to believe that no dissecting is done. There may be a stereopticon, but close observation will show no connections to allow of its use. In one state where a fixed supply of apparatus is required by the examining board, colleges were found with a full supply, but having no one who knew what the various articles were for nor who was capable of making use of them. There may be beautiful buildings or an abundance of dispensary and hospital material but an absence of proper supervision so that little use is being made of them. There may be a large, well-stocked library, but inquiry reveals that it is closed except for a few brief hours each week, or it is otherwise inaccessible to the students. A college may have an abundance of expensive apparatus in its laboratories, but investigation may show that enormous classes, not only in medicine, but in dentistry and pharmacy, may be crowded through the course in a wholesale manner bewildering to the student and very detrimental to his training.

On the other hand, a college may have a comparatively meager equipment, but there may be many evidences of careful oversight, showing that a splendid course, including laboratory training, is being given. So long as the equipment is being used, it is probable that the simplest, possibly home-made, apparatus is to be preferred, since the student will be more apt to provide himself with such apparatus and continue his laboratory methods after he goes into active practice than he would if his training was altogether with complicated and expensive equipment.

An accurate knowledge of foreign medical education should be obtained, not only to see how the standards abroad compare with those of this country, but that any strong points may be adopted and the weak places avoided. As before stated, this is a comparatively new country without a fully developed educational system. There will be much benefit derived, therefore, from a study of educational systems of foreign lands which are the result of several centuries of development.

The investigation should be an effort to obtain from all possible sources all the facts regarding medical education, bearing in mind that the teaching of medical students is the first work of the medical school. The chief aim in the fixing of any minimum standard should be that the finished product of our medical schools may be well trained and fully qualified physicians. Before any committee can draw up an acceptable minimum standard it must obtain complete knowledge of the weakness in our system of medical education as well as of the points wherein we excel, and the only way to obtain that knowledge is by a thorough investigation of medical education, including the actual inspection of every medical college.

Charity.—If all the money available for charitable distribution were properly expended, the suffering of the unfortunate would be much more largely limited than it is under present methods.—B. E. Nelson, in *Hygiene and Physical Education.*

THE METHODS AND THE OBJECT OF STATE EXAMINATIONS *

W. T. COUNCILMAN, M.D.
Professor of Pathology, Harvard Medical School; Member of Council on Medical Education, American Medical Association
BOSTON

In any discussion of this subject it would seem that at the outset certain general propositions may be stated to which all will agree. Certainly the primary object to be attained by an examination in medicine conducted by the state is to certify that certain individuals are capable of rendering useful service to the citizens of the state in matters pertaining to health. The law in this respect has a certain analogy with the pure food laws. The public realizes that it is unable to distinguish the false from the true, and places the matter in the hands of a committee or board who by proper methods of inquiry will make this differentiation and give the approval of the state to the true wares. In the pure food laws the differentiation is easily made by the application of tests, which, though they may vary somewhat in complexity and difficulty, are sufficiently accurate. When the objects of test are individuals instead of chemical substances, the test is much more difficult and the responsibility of the testing is much greater.

To these matters the general public which is the most concerned show an indifference which is founded on ignorance. Both the pure food laws and the medical-practice acts have been forced on a public indifferent and often distinctly hostile. Medicine is destined in the future, to a greater extent than it has in the past, to play an important, perhaps the most important, rôle in the social life of the people. Nothing is of so much importance to a nation as the health of its people and the vast possibilities of preventive medicine are just beginning to be appreciated. The realization of preventive medicine will be possible only when the present ignorance concerning disease and distrust of preventive measures are replaced by knowledge and confidence. It has seemed to me that a part of the distrust which has found expression in the satires of every nation is warranted, for medicine in the past has been influenced too much by dogma, by empiricism and superstition; even now these influences have not disappeared.

What are the qualities which we are warranted in insisting should be the result of the training of the student and which he must possess to render efficient service? I do not hesitate to give the first place to knowledge of methods and familiarity with their use and application. Modern medicine is, in fact, based on methods which enable us to find out what is taking place in the sick individual. We no longer conjecture, but we ascertain by the use of our senses and by methods which represent an extension of the senses. Medicine has advanced far on the path followed by the sciences, and the medical art is now to a great extent based on knowledge which in many cases enables us to predict. There is no longer conjecture as to whether a patient has a certain infectious disease, or whether there is a certain disease of the blood or the blood-forming organs, or whether digestion is taking place in a proper manner, but the problem presented by the sick individual can and should be definitely solved by the application of tests. The knowledge on which action is based must be derived from the sick individual; it can not come from books. The records of observations and experience are no doubt valuable, but the limitations imposed by such knowledge alone are enormous. In the first place, there are few diseases of which so accurate a description can be given that recognition of the disease is possible by a comparison of symptoms with the records. The actual diagnosis is not the final matter, for the treatment is directed not to the disease, but to the condition which the disease produces in the individual. The medical man must have such knowledge of disease as to know whether in a given case the disease may extend from the individual to others in his vicinity or remotely, in what way the extension takes place and how it is to be guarded against. In surgery there are not only the methods of diagnosis, but the chemical and mechanical methods of treatment. The medical man must not only be able to use all these methods, but must be able to make the deductions which are justified from the knowledge obtained by methods.

---

*Read at the Nineteenth Annual Convention of the National Confederation of State Medical Examining and Licensing Boards, Atlantic City, N. J., June 7, 1909.

We must go further. We are justified in demanding not only facility in the use of methods, their application and the proper use of knowledge gained by observation, but we also must demand thorough training in the fundamental branches of medical science. This for two reasons:

First, it is necessary in order that the student may acquire the habit of mind which will enable him to distinguish between proof and statement, knowledge and conjecture, which will lead him to appreciate new knowledge, and to strive constantly to increase both his own and the sum of knowledge. We are certainly much more appreciative of new knowledge at this period than ever before, and yet it has taken a long time for the body of physicians to become thoroughly aware of the fact that tuberculosis is an infectious disease. Such knowledge as that regarding the nature of malaria and its mode of extension, the mode of extension of yellow fever and of plague should extend much more rapidly than has been the case. When medical men have been called on to deal with situations in which knowledge of disease should have governed their actions and enabled them to cope successfully with the conditions, have they not frequently proved themselves to be ignorant or at least unappreciative of new knowledge? We might cite typhoid fever in the Spanish war, in which case there was certainly enough knowledge of the disease and the conditions of its extension to prevent the appalling loss of life, and the plague in San Francisco, the existence of which for so long a time was unrecognized or denied. Have we any assurance that the conditions of 1898 would not be repeated in case of another war? How much confusion remains as to the diagnosis of malaria and typhoid fever when their differentiation is so simple!

Second, the knowledge of the fundamental sciences is necessary because it is of constant use. The laboratory teaching which is becoming such a prominent factor in medical education gives the proper mental training and the objective knowledge. Medicine is a branch of biology in which the phenomena of living matter in an abnormal environment are studied. How ineffective must be such study when not preceded by study of the phenomena of living matter in a usual environment!

How shall these necessary qualifications be determined? It is obvious that the diploma of the medical school can not be accepted as evidence that the holder possesses the proper training and knowledge. If the state certifies to fitness it must itself determine this either by taking over the education, as in a state university, or by an examination. It has been found, however, that even when the state gives the education a final examination to test its character is necessary. In certain of the states some supervision of the medical schools is exercised through the board of medical examiners. There would seem to be no doubt that such supervision is capable of a salutary influence on medical education. There are two dangers connected with it:

1. It is difficult to make the supervision effective—to see that the medical schools really conform to the conditions imposed by the state board in their actual conduct and do not merely insert the conditions in their catalogues. It would be difficult to obtain any real idea of the state of medical education in the country by a diligent study of the catalogues of the schools. A catalogue is a very human production and, consciously or unconsciously, the imagination has a pretty free play in its formation.

2. If, on the other hand, the supervision is real and effective, it can easily be meddling. All who are engaged in teaching medicine must realize that medical education is now in a very unsettled condition. The subject-matter has enormously enlarged, and there is undoubtedly the attempt to teach too much, to hold on to the old traditional teaching and to add the constantly increasing new knowledge. Thirty years ago the only laboratory in the medical school was the dissecting room in which human anatomy was taught, usually by a man who had no conception of the general subject and who took the time for a course of lectures out of a busy practice, his anatomic teaching being, in commercial parlance, a by-product. The laboratory side has now developed enormously and there is a feeling which seems to be more prevalent in the laboratory than in the clinical teachers, that the laboratory unconnected with the clinic has been unduly developed. In the present conditions in our medical schools, in which there is, save in a few fortunate instances, no real amalgamation between the school and the clinic, no power of appointment by the school of its clinical teachers, it has been easier to develop the laboratories and to consume in them a large part of the obligatory four years. There is in most instances too sharp a separation of the laboratory and the clinic and lack of application to clinical problems of knowledge derived from laboratory work. There is less uncertainty with regard to the advantages of a preliminary training in science before medical studies are entered on, but there is much uncertainty as to the extent of preliminary training which should be demanded. Depend on it, those engaged in medical teaching will work out these problems better than an outside body. As I have looked over the requirements for examination in certain of the states it has seemed to me that the element of protection has entered into demands of some of them. A definite curriculum of study is demanded by some, and in certain instances the requirements directly conform to the scheme of medical education in the state universities. Certainly this serves an end, probably an important one, in bringing the entire scheme of legislative protection into disrepute, but this is not the end aimed at. After carefully weighing in my mind the advantages and disadvantages of state supervision and control of medical education, I think more is to be gained without it and that medicine had better be on a square free trade basis.

The most effective control combined with perfect independence in medical education can be exercised through the state board examination and on the character of this everything depends. The present method of these examinations is unsatisfactory and has about reached the limit of its usefulness. The examination consists in giving a number of questions on the different medical subjects, the answers to which are written out and afterward marked by the examiners. In conducting the examination there are various more or less elaborate rules, the reading of which gives one a rather pessimistic view of human nature, which are designed to prevent impersonation and other forms of cheating. Written answers to questions can not test the candidate's knowledge. They may test information which he has acquired from reading or lectures. They form no test of his power, of his ability to carry out methods of work, and to apply these methods in the treatment of disease.

I have recently examined a book compiled by Dr. R. M. Goepp and published by Saunders & Co., entitled "State Board Questions and Answers." The stated purpose of the book is "to provide a convenient compend for the use of those who wish to prepare themselves for the state board examinations." The material embraced in the 631 pages is selected from state board questions asked during the past four years, the preference being given to those asked in the larger and more representative states. The collection of the questions was undertaken by the publisher, the author, with the assistance of several persons named in the preface, being responsible for the answers only. The first impression on going over the questions is that they are rarely so framed as to bring out any exact knowledge in the answer. They are text-book questions compiled from text-books, which are themselves compilations. All of the old questions for which definitions of formal content could be given are there. The answers are generally unsatisfactory, often vague, often inaccurate. Many of the questions would really demand rather a discussion of a subject; from which discussion valuable information of the candidate's knowledge could be obtained, than a categorical answer. For instance, to the question, "Give a general explanation of the pathology of edema and include its chief factors," the answer is given in sixty words. Still, after an examiner had gone over 100 books, he would probably be thankful for the concise answers, even though in many cases it would be difficult to interpret their meaning. The book serves a valuable purpose in one way, for it ought to be possible for a good student well versed in examination methods, and with expert tutoring which would involve some elimination of unusual questions, to pass any written state board examination, after three months' close study—this without having ever seen a patient or the inside of a laboratory. Certain of the poorer medical schools, knowing that their men must pass the state boards or they must close their doors, have adapted their instruction to this end with great success; and such books as that referred to will prove a valuable addition to the library of both teacher and student. Whether the scrappy and often false information obtained by the study of such a book has any other value is uncertain.

The examination, to be effective, must be practical. The candidate must show, not what cramming, but what medical training he has had and what he can do with the knowledge he has obtained. At the first sight there would seem to be many difficulties involved in the change from the written to the practical, but they are not so serious as they appear to be. It has been found possible in other countries to base the grant by the state of authority to practice on an examination of practical character, and it seems really absurd to say it can not be done here. We have only to adopt methods which are practical, which have been tried and approved elsewhere. Such examinations would undoubtedly demand the use of laboratories and of hospitals for their conduction, but they could be obtained. Examinations should not be held in cities where such indispensable aids can not be obtained.

The simplest part of the examination would be in those divisions in medicine in which the instruction is given in laboratories. Arrangements could be made by the examiners for the use of the laboratories in which the instruction is given. All good schools require a practical examination in anatomy, histology and embryology, physiology, physiologic chemistry, pathology, and bacteriology, and no difficulty has been found in giving it. In all of these branches the examination would doubtless include the recognition and description of specimens, and the demonstration of ability to do the technical work demanded by the study. In addition to this, a few wisely chosen questions could be given to show that in addition to technical ability the candidate has some appreciation of underlying principles and of the bearing of the study. In anatomy a part of the examination should be devoted to the demonstration of regions on the living model. With these examinations could very properly be included the examination in clinical pathology, covering such matters as the chemical and microscopic examination of the urine, stomach contents, feces, blood, etc. For this last examination certainly more time would be required than for any one of the others and the marks given should be based on the time required and the importance of the subject. A student might very well be passed who had hazy ideas about bones, ligaments, and muscle relations, or who failed to detect the differences in appearance and structure of certain nearly related tumors or who had unconventional ideas as to cell origins, but inability to examine sputum, urine and blood should cause his rejection. With the time which is given in all schools to laboratory work we are warranted in giving a rigid examination in the laboratory branches and in demanding that the work should be of such a character as not only to give the necessary discipline, but to teach thoroughly those procedures which are to be used in practice and on which the accuracy of clinical work chiefly depends.

These examinations would consume not less than ten hours, with some leeway allowed to the slower men, and should be distributed over two days. The candidates could be divided into batches of twenty-five and the examinations conducted by one chief examiner and one assistant. In such an examination it would not be necessary to take any very elaborate precautions against cheating. The question very properly comes up as to what time in the medical course such an examination should be held. I think, on the whole, it would be better to allow candidates to take it either in the middle or at the end of the course. This would give the advantage of weeding out at an early period the men who were totally unfit and of allowing some who failed to go back and make up again. The candidate should be passed or rejected on the examination as a whole and not allowed credit for any single branch. I have estimated the expense of such an examination at $1,000 for 100 men examined at one period. This allows $25 a day for three days' work of the chief examiner and $15 a day for the same time of the assistant, and $160 for general expenses in providing apparatus, etc. It is possible that this is too little, but for many reasons it is not desirable to place the remuneration of the examiner at too high a figure, and the element of rendering service to the state should enter into the compensation.

The second part of the examination embraces the purely clinical. It should be thorough and practical. It will be necessary to have patients and to make some use of a hospital. The patients may be selected chiefly from the dispensary ambulant material, and among these cases can be found illustrative of the more common diseases of organs. The candidate should be given the necessary appliances, chemical and physical, to be used in diagnosis and should show not only his ability to use them, but to understand their use. How much use would be made of acute cases in the wards is uncertain. Certainly in the beginning of this method of examination it would be well to excite just as little opposition as possible. Any objections on the part of the patients themselves to their being used for examination purposes could be easily overcome by a small fee. It would be well, of course, to include with the sick a certain number of the normal. The examination in surgery also would offer no difficulties. Numbers of surgical diseases can be found in the ambulant material, both acute and chronic conditions, which could be diagnosed, described, and treatment indicated. Certainly a part of the surgical examination should consist in the preparation of a patient for an antiseptic operation both under conditions in which all appliances are at hand and under more primitive conditions likely to be encountered. The examination should also deal in some measure with psychiatry, that greatly neglected branch of medicine. It is entirely possible either to take the candidates to an asylum for examination or to use cases which could be brought to the examination rooms. The candidate should demonstrate his ability to diagnose the more common forms of insanity.

It is probably not possible to conduct a practical examination in obstetrics and gynecology. In obstetrics the manikin can be used with advantage, but this would have to be supplemented by the written or oral examination. It might be possible to introduce a few cases of early pregnancy among the ambulant cases and have the candidates understand that they might be required to examine such a case. Just as in the primary laboratory examination certain questions might be asked for written answers, and it would be much better that histories, diagnosis and treatment of cases assigned should be written. I do not think it would be necessary to conduct special examinations in the skin and other specialties. Among the cases selected, patients illustrating many special pathologic conditions could be included and given out for examination. The candidate could not tell whether he would receive a case of psoriasis or laryngeal tumor, diabetes or chronic disease of the kidneys or liver. In any case it is essential that he be given the apparatus for diagnosis and opportunity for its use.

The examination in hygiene would be partly covered by the examination in chemistry, bacteriology and physiology, and if all the other examinations were successfully passed it might be assumed that the candidate would know the most essential matters in the subject. Such an examination would probably consume ten or twelve hours, and for 100 men examined in groups of twenty-five would extend over three days and would probably require six chief examiners and six assistants who would receive the same compensation as in the first examination. I have thought that such an examination, allowing liberal compensation for patients, for use of apparatus, etc., could be held for $1,500 for 100 men. This gives the cost of the entire examination at $25 per candidate. This is, of course, the bare cost of the examination with a proper compensation for the examiners, and it does not seem to me that there should be much additional expense. A permanent secretary who would have to give some part of his time to the work would be necessary, and some expense in addition would be incurred. I see no objection whatever to raising the fee sufficiently to include such expenses. The fee with a corresponding lengthening and increase in the efficiency of the examination might be made $50 or even $100. Of course, difficulty would arise in regard to the medical sects, but these sectarian differences chiefly or only concern therapeutic measures, and the sectarian candidates who had successfully passed the other examinations could be turned over to sectarian examiners for the therapeutic examination. No osteopath, homeopath, eclectic, hydropath or Eddyite could object to their candidates being required to show practical knowledge in anatomy, physiology, chemistry, clinical methods, and the general features of disease. Certainly we would feel that such men were to be trusted, no matter under what banner they chose to serve.

The final examination should be given to candidates only who have successfully passed the primary. Whether the two examinations are taken separately or together may be left to the choice of the candidate.

The objections which have been urged against this practical examination have never concerned the real question as to whether or not it is the best method, but have been mainly on the score of expediency. I can not help quoting the objection urged by the president of one of the state boards. He says:

> "We examine for instance at a single examination four hundred applicants. All of you gentlemen I take it are practitioners of medicine; are there any of you who have had a patient in the hospital that you would be willing to have these four hundred men pound on the chest to ascertain the condition of his lungs, or to see whether he had a heart lesion or not? I don't think you would."

Such objection does not have to be met. At any rate his board could not give a practical examination for the fee demanded, $10. Another objection is on the score of expense. I have shown that the examination can be held for the fee charged by most of the states and the examiners paid. It is absurd to think that men capable of giving a proper examination can be obtained without compensation. A third objection is that the examination will take more time than the written; and this, of course, is true. But the candidate at about this period of life has plenty of time, the examiners are compensated for their time, and the thorough examination has great educational value. A fourth objection which has been urged is that the candidates may be known to the examiners and favoritism shown. This is a pretty low objection and it does not hold, for there are many examiners, and a candidate who passed one examiner by intrigue or favoritism would be pretty sure to be rejected by the others. If a candidate has the qualities which would incline all the examiners to favor him regardless of the knowledge shown, he might be a useful man in the profession.

The last objection, and probably the most serious, is that the state boards as at present constituted are incapable of holding such examinations as are here indicated. The men in every state who are most capable of conducting proper examinations and who have hospital and laboratory connections which afford facilities are generally teachers of medicine, and as such are excluded from examining boards, and there is some justification for this. Men who have been a number of years in practice and who have not had special training are incapable of holding proper examinations in many of the subjects in medicine. I regard the examination as the most difficult part of my work; and how can a man without special training examine in such subjects as anatomy, physiology, bacteriology and pathology? The difficulty, it seems to me, could be met by appointing men as examiners who had made themselves capable by a special training to this end. Among the recent graduates of medical schools, men perfectly capable of acting as examiners or who could make themselves capable by work directed to this end can be found. I hold, however, that if a man has not had the training and has not the knowledge which qualifies him for the position of examiner in a subject he should not accept the position if offered him.

I can not close this paper without apologizing for my temerity in offering advice to men who have a most difficult position to fill and whose work has been faithfully performed and of great benefit to the public, to the medical profession, and to education. But it has seemed to me that by a somewhat radical change in the method a very much greater amount of good can be accomplished. The position on the state board of examiners is one of great responsibility, for on their action depends the value of the relation between medicine and the public, and they hold in their hands a lever of immense power; in fact, they are the chief agency for the uplift of medical education. At the present time there is no medical position in state or university which is of equal importance and responsibility. I know that there are difficulties in the change in the method of examination which I have advocated, but the difficulties are not so great as those which were in many states overcome in the establishment of medical examining boards.

These difficulties may not be overcome at once, but they finally will be. Let us convince ourselves that we want to find out whether or not a man can do properly the things which are demanded in the practice of medicine, and that we can not find this out by asking a question and requiring a written answer, but we can demand that he show us his ability. We would not test a bricklayer's ability by questions and written answers, nor can we test any art in the same way. A painter must be able to paint; whether he can describe the process or not does not much matter. Medicine is an art, and its success depends on the proper use of many methods. I am further convinced that it is most important to begin the change in examination methods and to begin along the line of least resistance, adding more and more subjects at each examination. I will not admit that the plan is not capable of being carried out, and it is our part in every way to assist the state boards in carrying out their arduous task.

THE MOVING PICTURE SHOW

A NEW FACTOR IN HEALTH CONDITIONS

HOWARD D. KING, M.D.
NEW ORLEANS

The development of the cheap moving picture and musical theaters as factors in the health of the community seems to have escaped the notice of the medical press. To-day every village and hamlet in the United States boasts a moving picture show. In the large cities of the north and east it is not unusual for a hundred and often more to be in operation. In Europe they are outnumbered only by the public houses and cabarets. As is well known, the great majority of these theaters exist where the population is greatly congested, as in tenement districts and laboring settlements. The reason for this is obvious. It is the patronage of the poorer classes which makes the moving picture industry a paying proposition. These cheap theaters are usually located in old rookeries or poorly paying commercial sites, as abandoned shops of small tradesmen, etc. In the construction or building alteration of these places for their special needs the one object in view is to obtain a maximum seating capacity in as small a space as possible. No attention whatever is paid to ventilation and not the slightest heed given to the simplest sanitary details. The health or comfort of the patron is a secondary consideration. Municipal regulation is limited to fire prevention and safety exits—and this only after several serious catastrophes.

The performances are continuous, and thus an ever-moving stream of humanity, constantly passing in and out, stirs up dust and dirt that verily reeks with tubercle bacilli. The programs in these resorts have been considerably lengthened owing to the keenness of competition. The result is that an audience is confined within these ill-ventilated and poorly sanitated amusement resorts often for more than an hour and a half, breathing in air which has become befouled and disease-laden through lack of sufficient air capacity. The superabundance of carbon dioxid and organic matter in the air gives rise to sick stomach, headache and a drowsy feeling. The small fee of admission is responsible for a class of patronage which is entirely oblivious of the simplest health precautions. Spitting on the floor is a common practice and is allowed to go unnoticed. Signs calling attention to the dangers of the vicious habit of indiscriminate expectoration are rare. The use of the electric fan in certain of these resorts, while refreshing to the overheated patron, also serves to dry up the sputum with greater dispatch, thus increasing its disease productiveness. Cleaning the premises is impossible during the hours of operation, which gives some idea of the amount of filth that accumulates.

Robust and vigorous individuals employed as singers and musicians, appearing as often as twelve and thirteen times a day in these crowded resorts, soon undergo a remarkable change of health. Poor ventilation produces not only discomfort and loss of energy, but greater susceptibility to disease, especially tuberculosis. Many of the singers are raw amateurs and know nothing of the care and preservation of the voice, and in many instances a voice capable of greater things is lost to the public through exposure to such unfavorable conditions. Laryngeal troubles are a frequent source of annoyance to this class of people through excessive vocal effort and constant confinement. I have treated many of the singers employed by the cheap moving picture shows and found the majority of them to be of a decided phthisical tendency. The film operator who is confined in a small cubby-hole at an exceedingly high temperature falls an easy prey to tuberculosis. Constant attendance at the scene of employment, coupled with the irregularity of meals and uncertain hours, is responsible for the fact that many of the male artists become alcoholics. Taken all in all, the cheap moving picture theater artist has no easy task and sooner or later another victim is enrolled under the banner of the white plague.

The general practitioner is often consulted by a patient complaining of headache and burning eyes which run water as soon as they come in contact with strong light. After a thorough examination, including urinalysis, the patient is referred to an ophthalmologist in order that a refractive error may be corrected and the patient relieved of the headache and the visual irritation. In a great number of cases the ophthalmologist will report that there is no error of refraction and that he is unable to account for the headache and the running burning eyes. An inquiry into the habits of the patient will elicit the information that he is a devotee of the moving picture show. The constant gazing on a rapidly moving and scintillating film with every mental faculty alert to maintain the connection of the story is sufficient to produce an eyestrain of great severity and thus cause headache and burning eyes. The only remedy is rest and cessation from this form of amusement. After a few weeks vision becomes normal or nearly so and no ill results are experienced unless the patient resumes his former habits. In many cases the eye trouble assumes a severity that calls for long and persistent treatment on the part of the ophthalmologist.

Moving picture shows in tenement districts and labor settlements should exhibit pictures that tend to elevate the mind and improve the moral condition of their audiences. Pictures portraying scandal, illicit amours and criminal cupidity very often have a debasing effect on a mind that is already morally warped through environment and surroundings, thereby bringing to the surface a latent criminality. If the moving picture shows are to remain, radical changes must be made.

Rigid inspection by the health authorities is absolutely necessary. Proper ventilation by means of exhaust air fans, airifiers and other ventilating appliances and numerous apertures with sufficient air intake must be provided. The number of cubic feet of air necessary for health should be determined by the seating capacity. The flooring should be oiled, not carpeted or covered with dust-gathering material. Plush-covered and velvet-covered seats should also be prohibited for obvious reasons. Suspension of the performance at the end of every five hours, when the orchestra or seating hall should undergo a thorough cleaning, is of urgent necessity. The cleaning could be accomplished within forty-five minutes by the aid of the vacuum cleaner and should be followed by a draught of pure air throughout the place, if possible. At the termination of the day's performance the whole resort should be given the proper sanitary attention. Signs should be conspicuously posted as to the evils of spitting.

CONCLUSIONS

That a great deal of eye trouble is due to moving picture shows can not be denied. The singers, musicians and film operators of these resorts fall an easy prey to tuberculosis through excessive vocal efforts, constant confinement, irregular habits and long hours. As a disseminator of tuberculosis the moving picture theater ranks high and it will become necessary to enact special health laws to remedy the evil.

HELP THE MOTHER NURSE HER CHILD

A PLEA TO PHYSICIANS NOT TO BEGIN ARTIFICIAL FEEDING WITHOUT FIRST TRYING TO HELP THE MOTHER MAINTAIN HER MILK SUPPLY *

MAURICE OSTHEIMER, M.D.
Instructor in Diseases of Children, University of Pennsylvania
PHILADELPHIA

That no artificial food can take the place of breast-milk has always been admitted, even by those who have had the most success with artificial feeding, men like Holt[1] and Rotch.[2] In some parts of this country, however, it is uncommon to see any attempt made to induce a mother to nurse her child, even when her breast-milk has not been examined to see whether it was abnormal or not. Is this not chiefly our fault—that is, the fault of the physicians?

Not only are no efforts made three to four days after birth, but later, when the child is between three and six months old, breast-feeding is often stopped for no apparent cause, here again without examination of the milk to find out its composition. Would it not be more just to the infant first to try to help the mother so improve her supply of breast-milk that there may be enough for the child, for some months longer, at any rate?

Baginsky[3] states that any other food than woman's milk requires considerable work from the infant. Chapin[4] declares that "normal maternal milk supplies the necessary quantities of fat, proteids, carbohydrates, etc., for proper structural development and maintenance of the vital processes, in forms that automatically adapt themselves so as to develop the digestive functions of the growing animal." Rotch,[5] with interesting detail, gives the principles, diet and exercise chiefly, which produce variations in mothers' milk, basing his results on frequent examination of the breast-milk in question. Holt[6] also discusses the value of food, drink and exercise in bringing about changes in breast-milk. He lays stress on examinations of the mother's milk also. Griffith[7] says:

> The possibility of improving the quality or quantity of breast-milk must never be forgotten before weaning is advised. An alteration in the diet, in the quantity of liquids taken and in the amount of exercise employed will often attain the result desired.

Morse,[8] in a most interesting article, says:

> The nursing woman ought to lead her usual life and not be treated as an invalid. . . . She should take her usual food, but more of it. . . . She must have light and air and must not be shut up in the house. . . . The best method of increasing the quantity of breast milk is the use of the breasts. . . . Within reasonable limits, the more taken, the more there is produced. Other methods are entirely subordinate. Among them may be mentioned, first, improvement of the general condition; second, a liberal diet.

Jaschke,[9] in his excellent monograph on the importance of breast feeding in the struggle against infant mortality, ridicules any special article of diet or

drugs, referring to Finkler's list,[10] and states that the best galactagogue is the nursing infant. He insists only that the nursing mother be well nourished. Schlossmann[11] and Engel[12] believe that the nursing mother may eat whatever she pleases.

Notwithstanding these and other unquoted opinions, it has been my lot to find that much could be accomplished in every case by persuasion, encouragement, advice and perseverance, even though the mother dislikes the idea of nursing her child and decides not to do so. Later, when the baby is several months old and the mother believes her milk no longer to be as nourishing or as plentiful as it had formerly been, much can again be accomplished if directions are correctly carried out.

Old as is the recognition of the fact that every well woman ought to nurse her baby (and only recently Walcher[13] has shown that no actual diminution in the ability of women to nurse their offspring can be demonstrated anatomically) it was never so important as at present when the success following the use of cows' milk mixtures (and, unfortunately, the popularity of the proprietary infant foods) have made the use of the infants' bottle seem almost a necessity. That one or two bottles daily, given when the baby takes his nap, or to allow the mother time for fresh air and exercise, can do no harm has been shown by many careful observers, provided the mother follows other directions rigidly.

Since the appearance of Dr. Southworth's article[14] on this subject, in 1902, I have urged all those with whom I have come in contact, socially as well as professionally, to continue breast-feeding until the baby is at least eight or nine months old. In contrast to the subjects observed by many in cities, the mothers I have treated have been normal women or nearly so, and on this account, perhaps, my directions have resulted successfully.

During the last few months of pregnancy, not only should the nipples receive daily attention, but every pregnant woman should cultivate the excellent habit of drinking water. It is well to have a pitcher of drinking-water always near at hand so that she may drink frequently. She should learn to drink without discomfort three quarts or more every day. The value of large amounts of drinking-water during pregnancy has also been urged by Holloway[15] as tending to prevent the toxemias that so readily occur from retained products of metabolism. Other rules of decided importance during pregnancy are: exercise in the open air, a walk or drive, or in bad weather a walk on a piaza or in a room with windows open; sufficient sleep, not only eight to ten hours at night, but also a nap of two or three hours every afternoon; correct, wholesome, plain food and enough of it (red meats to be taken sparingly); and the regular daily evacuation of the bowels, brought about by regulating the food, water and exercise, although it is sometimes advisable to add some mineral water, besides.

After delivery it is most important that the mother take daily three or four quarts of water, some with meals and a great deal between meals. This is not difficult if the woman has grown accustomed to drinking large amounts of water daily during pregnancy. Tea and coffee should be absolutely prohibited during lactation. Next in importance should come the thin corn-meal gruel advocated so strongly by Dr. Southworth. This is easily made, boiling one or two tablespoonfuls of yellow corn-meal in a quart of water for five hours, in a double boiler, with the lid on. It may be flavored by putting in ten or fifteen large raisins, a little salt, wine or nutmeg. It is kept on ice and drunk between meals, poured on ice in a bowl or glass, at 10, 4 and bedtime. The taste is not bad and most women like it. For those few women who like milk and are used to drinking it, a quart or more may be allowed daily; but milk should never be urged on those who dislike it or believe that it disagrees with them. *In such cases cocoa prepared with milk may be substituted.*

In many women with a tendency to anemia during lactation, the use of one-third or one fourth of a bottle of brown stout (imported), not more, taken with the midday meal occasionally seems of value. Ale, beer and malt extracts are not good, as they tend to obesity, without affecting the milk or the general condition of the woman. In a few of these anemic mothers some iron preparation, such as the phosphates, glycerophosphates or hypophosphites, has seemed of decided benefit. As before delivery, exercise, fresh air, sufficient sleep, enough food, regular bowel movements and a routine existence are to be insisted on. It should not be overlooked, however, that an active cathartic will greatly, though temporarily, diminish the amount of milk secreted. Great stress must also be laid on the regular care of the breasts, washing them both before and after nursing.

Though Jaschke[16] says there is no absolute contraindication to nursing, most medical men prefer not to allow a mother with advanced tuberculosis to nurse her child; and other conditions in the mother may rarely exist which would make nursing injudicious for her. There is a group of nervous women found in cities especially in whom all efforts are apparently wasted, the women growing stout without any improvement in the milk-supply being noticeable. Dr. Southworth's suggestion[14] to give the child both breasts temporarily, alternating with one or two bottles a day, when the mother first begins treatment, will be of value in some serious cases. By this means the mother's supply of breast-milk may be saved.

My notes cover 73 cases, including private and hospital patients during six years. In 24 of these my directions were not followed, or they were carried out incorrectly or for only a short time. In 6 of these cases the mothers were neurotic and grew stouter without any noticeable improvement in the milk. The mothers have carried out directions in 49 cases and have been able to nurse their children to between six and eight months. Directions were given before the birth of the child in 21 cases; in 14 cases the infants were under three months of age when treatment of the mother began; in 9 cases they were from three to four months old; in 5 cases, over four months of age. In only 6 cases was one bottle allowed daily; in 2 cases two bottles were given daily.

At some time between six and eight months the great majority of mothers noticed that their babies cried more than formerly and they soon realized that this was due to hunger. When this occurred, in spite of having conscientiously carried out directions, weaning was first considered. By this time most babies were being nursed at 6, 9, 12, 3 and 6; or possibly at 6, 10, 2 and 6, with one night feeding. A cows' milk mixture was first substituted for the afternoon feeding, as most infants appear to take least at that feeding. The first mixture given was composed of 1 ounce of boiled water (or barley-water), 1 ounce of lime-water and 2 ounces of milk (4 per cent. certified, from which the upper 6 ounces from a quart bottle had previously been removed by dipper). After heating the mixture, it was in most cases given with a spoon; in a few cases, those used to bottles, the baby's bottle was again used. For colicky infants the bottle is to be preferred; and a hot-water bag may be applied to the abdomen during and after feeding. A few days later, when the infant learned to take the entire 4 ounces, the amount given was increased to 5 ounces; then gradually to 6, 7 and 8 ounces, still using one-half milk, with the upper 6 ounces dipped off a quart. By the time the baby took 6 or 8 ounces at each feeding, the milk mixture was substituted for the breast twice daily; in a few more days, for three feedings, and by the end of three weeks the infant was weaned. Then, instead of removing the upper 6 ounces from the quart, only 5 ounces were dipped off; later only 4 ounces.

The baby has now learned to digest the proteid of cows' milk and is learning to tolerate the fat; the strength of the mixture is gradually raised, although it is unwise to exceed 6 ounces of 4 per cent. certified milk (still with the upper two ounces dipped off each quart bottle) in an 8-ounce mixture, 7 ounces in a 9-ounce mixture, or 8 ounces in a 10-ounce mixture, until the child is one year old. Then orange juice and a cereal, such as strained oatmeal, well cooked, may be begun; later, junket, custards, dry toast, soft-boiled egg, etc., may be added. Well-baked potato and baked apples are favorites with some babies.

While special stress has been laid on the feeding, ordinary hygiene should by no means be neglected. The child, as well as its mother, needs fresh air, baths, drinking-water, regular habits of sleep, defecation, etc.

The object of this paper has been simply to reiterate the immense importance of breast-feeding and to report my results, achieved by persuasion, advice, encouragement and perseverance in the overcoming of difficulties, few of which are found on investigation to be as real as young mothers think them. That this experience may help others to obtain like results is my hope, so that every woman may try, for a time at least, to nurse her offspring, an act which is sure to be followed by a generation of stronger individuals and by a great decrease in infant mortality.

118 South Twenty-second Street.

ABSTRACT OF DISCUSSION

Dr. H. M. McClanahan, Omaha: As the school question is of importance after the child is brought into the world, and reaches school age, this question is of importance in saving the child to enable it to live to school age. Recently I have been asking mothers why they weaned their babies, and when they weaned them. Sixty per cent. of the mothers replied that the family physician had told them to do so. Many weaned them within the first two weeks of life because the child cried. Without knowing why it cried it was put on the bottle. I am an advocate of mixed feeding rather than leaving the child without breast milk altogether. If a child is given the breast part of the time, I think the mother is entitled to give it the bottle a part of the time. Breast milk makes the baby more resistant to infections, but our knowledge of mixed milk makes it easier to have a baby partly on the breast and partly on the bottle. The mother should be taught that nothing but organic disease justifies a mother in weaning a baby. If necessary she may give it the bottle as a supplement to the breast feeding if the child does not get enough milk. In text-books on the diseases of children ten pages are given to the subject of artificial feeding and almost nothing to breast feeding and how it may be brought about. Frequently mothers will say to me: "I understand that it is just as well to feed the baby on the bottle." Recently I saw a baby on the fifth day of life. It had a temperature of 105 F. The mother was a primipara. She told me she was sorry she could not feed the baby. By keeping the baby persistently at the breast she is now able to nurse the baby. Those are the questions that lie at the very foundation of the supply of human beings. Seventy-three per cent. of the children in the large cities are foreign born and are nursed by their mothers.

Dr. J. P. Sedgwick, Minneapolis: It is gratifying to see that we are coming out of a state of pessimism in regard to mothers nursing their babies. I have kept a record of private cases I have had since I began practice, as to whether the mother nursed her child and, if she stopped, why, and when she stopped. Some of the answers are so ridiculous that it would surprise most of us if we kept such a record. In the first place, we are led to believe that it is very frequent that breast milk does not agree with the baby. That I believe is a rare condition. I think it is usually a quantitative question rather than a qualitative one. Let me recite one example. A baby had been taken from the breast and put on the bottle on the advice of a physician who had examined the mother's milk, reckoning the amount of cream and protein. The physician found 4 per cent. of protein and for that reason thought that the baby could not be kept at the breast. He got doubtful results when the baby was put on the bottle and very soon the baby and its mother came to me. I could see no reason why the child should not be nursed by its mother; I examined the milk and I got 1.4 per cent. protein in two samples, showing how much harm can be done by inaccurate examinations, and then basing our therapy on such examinations. I am so convinced that it is a general quantitative question that I have scales not only in my office, but other scales that are sent from house to house, allowing the mother to see for herself what the child gets. We should have very accurate data before we take a child from the breast.

Dr. L. Duncan Bulkley, New York: For years I have fought for mothers nursing their children. I have not used the scales and I have not analyzed the milk. I am an old-fashioned practitioner, but I am positive that attention to the mother has accomplished results that could not be secured otherwise. Over and over again a mother comes to me and tells me she can not nurse her child. I analyze the urine and examine the mother carefully, and find metabolic or other errors which I correct, and in nearly every instance the mother is given iron. In eczema in small infants I give the mother arsenic and iron and seldom give the child anything internally. Time and again people have spoken of the fact that when I stopped the mother from taking tea the child's eczema stopped. I have seen so many cases of eczema in children in which the mother was given stout, and in which the eczema was cured when the stout was stopped, that I can not help believing that the stout has something to do with the eruption. I believe mothers can be educated to drink milk, but I never give milk with the meals. The mother drinks the milk like water, one hour before her meals. I think the milk should be warm, so I commonly dilute it with one-third of boiling water. The mother's appetite is increased thereby, and the milk does not to my belief, go through the stomach in the usual way: I believe it is absorbed. My directions are that the moment the mother awakens in the morning she should drink eight ounces of milk, with one-third hot water, and that she repeat this one hour before each meal. She should let four or five hours pass after the ordinary meal before taking it. The idea is to supply the mother with milk which she gives the baby.

Dr. A. F. Furrer, Cleveland: The frequency with which the mother should nurse her baby is important. It is common experience that mothers nurse their babies too often. "Every time it cries" is the admission (during the day and all night long). At the Babies' Dispensary and Hospital in Cleveland, the four-hour intervals, after the German method, is in vogue and works very nicely. I believe that if we as physicians instruct the mothers to nurse *infrequently* more mothers would be willing to nurse their babies.

Dr. Charles Douglas, Detroit: A little confusion has arisen by not drawing the line between the normal child and a delicate child. Those of us who give most of our time to correcting the damaging results due to our feeding, realize that success depends on recognizing that the digestive power is only so great for each meal and we have to get in enough nutrition within twenty-four hours to meet the needs of the child. We must give the child at each feeding the amount it can digest perfectly and get a proper stool. Then when it becomes hungry we must feed it again regardless of the time since last meal. To be successful we must recognize that fact. I did not notice whether or not the essayist had made any provision for the dilution of the food. I am in the habit of weaning children by gradually introducing a starchy diet. Dr. Ostheimer's plan would certainly appeal to any one doing this work.

Dr. John Lovett Morse, Boston: Dr. Ostheimer has read his paper before the wrong audience. He should have read it before obstetricians or nurses. The pediatrists are now all awake to the necessity for breast feeding.

Dr. Frank P. Gengenbach, Denver: Every day, every week, every month, that the child receives breast milk increases its resistance in the battle for existence which no other feeding method makes possible. This is the teaching of Salge, the professor of pediatrics at Göttingen. The Germans try in every way to give breast milk. They would no more have an infant hospital without wet nurses than they would think of having such a hospital without the infants themselves, because they have so many babies who can not be fed in any other way. Some babies will only get along with bottle feeding if that is supplemented with breast feeding, and others can only get along on the breast. The Germans recognize only one contraindication to breast feeding and that is tuberculosis on the part of the mother. Even in cases of mastitis they do not consider it a contraindication, even if a slight amount of pus is present. They believe that so long as the mucous membrane of the throat and mouth are intact there is no danger of infection. For that reason they object to mouth washing because they believe more harm results from the abrading of the mucous membrane than good can come of the mouth washing.

Dr. Thomas S. Southworth, New York: In the diet of the nursing mother I believe that milk as a milk maker stands first. Second to that, I place cornmeal gruel. I do not use the latter in such large quantities as formerly. I find that about four tumblers of an equal mixture of gruel and milk are enough, giving the rest of a quart of milk at other times. This gruel should be cooked long to take off the raw taste, and salted to prevent a flat taste; then it should be mixed with milk and it is for most people fairly palatable. When the supply of breast milk is small and weighing shows that the child does not receive enough milk to satisfy it, much good is done by nursing it each time at both breasts. Again, if the fat is high there is less fat from the first milk of breasts than if one breast is stripped. When the number of breast feedings and supplementary feedings are equal, it is imperative that each nursing be from both breasts or else the amount of milk decreases. I am not in accord with one writer who claims that the giving of one or two supplementary feedings to a nursing infant involves a diminution of the breast milk. On the contrary, I think that it often tends to build up the breast milk rather than to decrease it.

Dr. Maurice Ostheimer, Philadelphia: I appreciate Dr. Morse's suggestion, for I think the obstetricians are largely to blame. While I realize the value of milk as a food, there is no doubt in my mind that it will cause indigestion in many women, even a very little of it. I have never tried Dr. Bulkley's method, but will do so.

Playground Space.—The London school authorities have determined that fifty square feet is the minimum playground space for each child.—*Hygiene and Physical Education.*

MIDDLE MILK MIXTURES *

ALFRED F. HESS, M.D.
NEW YORK CITY

It is some years since it was shown that when milk is allowed to stand the bacteria are carried upward with the fat globules so that the cream layer contains a far greater number of micro-organisms than the underlying skim milk.

This teaching has been corroborated many times, although it has been frequently forgotten in practice and in experiment. In a study published about one year ago,[1] from the Research Laboratory of the New York Board of Health, I went somewhat deeper into this question, in which by chance I had become interested. As some of those present are acquainted with this investigation, I shall not review the experiments which I undertook in this work. Briefly stated, they resulted in establishing a fact which had not, I believe, been previously noted, namely, that the bacteria which the cream is known to harbor, are not homogeneously distributed throughout its depth, but are present in far greater numbers in the surface cream than in its lower strata. In other words, it is incorrect to regard the cream as a unit when we are considering its bacterial content. It was frequently evident from a glance at the Petri plates that the uppermost two ounces of the bottle contained decidedly more bacteria per cubic centimeter than the succeeding two ounces, and these, in turn, more than the lowest portion of the cream or milk (Table 1). This was true even when the milk was simply poured from the bottle. Tubercle bacilli also were shown to be carried to the surface, for the animals inoculated with the upper two ounces of cream developed tuberculosis oftener than those inoculated with the lower ounces. As typhoid fever of late has been frequently traced to the milk supply, I took the opportunity recently of inoculating with typhoid bacilli two bottles of a certified milk, which at times is almost sterile, and, after allowing them to stand over night, made bacterial counts from the various layers. As was to be expected the result was the same; the greatest number of typhoid bacilli were found in the upper two ounces of the cream (Table 2). This result preaches its own remedy.

TABLE 1.—Bacteria Per c.c. in Layers of Bottled Milk.

1st 2oz.	2nd 2oz.	Remainder.
93,500	49,000	
86,500	14,000	
235,000	96,000	40,000
115,000	36,000	6,000
102,000	57,000	
1,383,000		160,000

TABLE 2.—Typhoid Bacteria Per c.c. in Inoculated Bottled Milk

1st 2oz.	2nd 2oz.	Remainder.
320,000	103,000	43,000
1,200,000	395,000	155,000

In the paper to which I have referred I suggested a way of taking advantage of this physical principle and adapting it to the practices of infant-feeding. This new modification of preparing milk was not complex and did not clash with the accepted method of estimating top-milk mixtures, for, after discarding the upper two ounces of cream, it was ascertained by quantitative analyses how many ounces should be removed to obtain 12 per cent., 10 per cent., or 7 per cent. cream; in other words, the different strengths of cream which are used as a basis for preparing top-milk mixtures.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

[1] The Distribution of Bacteria in Bottled Milk, and its application to Infant Feeding. Arch. Pediat., August, 1908.

Nevertheless, in spite of its basis of scientific fact and apparent practicability, this partially skimmed milk which I now term "middle milk" has, so far as I am aware, found no acceptance. In the recent literature are found references to the usual top-milk mixtures as frequently as before, some writers urging the use of the upper two or four ounces of the gravity cream for milk mixtures, or even the use of the uppermost cream from two or more bottles. No argument against the theoretical or practical soundness of my suggestion has come to my notice. As I have found this modification of top-milk feeding practicable in a clinical experience extending now over a year, I thought it excusable to point out in a few words that middle milk is not merely an interesting laboratory suggestion, but that it permits of a simple and practical modification of top milk feeding, and one which possesses decided advantages.[2]

I have used the middle-milk mixtures mainly in the dispensary, prescribing them to women who are certainly not endowed with more than average intelligence. These mothers were given the following directions: Remove the upper two ounces of cream and keep it for table use. Then dip off the next eight ounces of milk. (This furnishes them with a standard 10 per cent. cream.) They are then directed to dilute a certain number of ounces of this cream with water or barley water according to the age or condition of the infant. If a 12 per cent. cream is preferred as a basis, 7 instead of 8 ounces of middle milk, is ordered removed; if a 7 per cent. cream is desired, 12 ounces are removed. It is certainly a very simple matter to carry out these directions. The only possible disadvantage is that there are fewer ounces of cream as a basis than in top-milk mixtures; for example, whereas we are able to obtain 16 ounces of 7 per cent. top milk from the bottle, we can have only 12 ounces of middle milk. The mothers understood the directions readily, quite as readily as they did the formulas based on top milk which I had been in the habit of prescribing.

We are all aiming at supplying better milk for the infants of the poor, and are striving to make it possible to obtain, especially during the warm weather, a cheap milk with a low bacterial count. Here, then, is a supplementary method by which the count may be materially reduced without in any way affecting the natural properties of the milk.

We can not hope to obtain clean "middle milk" from dirty whole milk, but it is certainly true that the more contaminated the milk the more is to be gained by removing the upper two ounces. And, on the contrary, the better the milk, that is to say the more nearly it approaches the standard of certified milk, the less is to be accomplished by this process. At present there can be no question but that comparatively little of the milk fed to the infants of the large cities approaches this latter standard. If the milk is contaminated by pathogenic bacteria, for instance, by tubercle or typhoid bacilli, the dose of these bacteria fed in the "middle milk" will be much less than that in the top milk.

I realize that many here have made use of middle milk, although they have not used middle-milk mixtures, that they have, for perhaps years, prescribed the removal of the upper ounces of the cream in order to reduce the fat content of the milk. In this way they have unconsciously killed two birds with one stone, and the fact that the modification which I suggest chimes well with the teaching against high fats should argue strongly in its favor. Especially is this so as regards feeding in warm weather, when bacterial and fat intoxications woefully combine to increase the infant mortality.

I do not urge this modification as a method of purifying dirty milk, as a substitute for pasteurization or sterilization, but wish merely to call the attention of those who prescribe cream dilutions to the fact that "middle milk," that is bottled milk deprived of its upper two ounces, not only contains fewer bacteria than top milk, but has been found of practical value in the feeding of infants.

154 West Seventy-second Street.

ABSTRACT OF DISCUSSION

Dr. Frank S. Churchill, Chicago: I take it that the point in feeding babies is first of all to feed them clean milk and then to feed them percentages that are adapted to the child. These two objects can be better attained through the milk laboratory. It is true that the milk laboratory is an expensive thing, but in all the larger cities we have charitable milk laboratories where such milk can be obtained at a very small cost and in case of need it can be obtained free. We can send the prescription to the laboratory and give directions as to the exact amount to be fed to the child. The laboratory at Chicago is inspected and subjected to bacteriologic investigation and we feel that we can depend on the milk from this laboratory.

Dr. L. T. Royster, Norfolk, Va.: The feeding of babies, especially babies of the poor, resolves itself into getting clean milk. In Norfolk we have greatly lowered the mortality by getting clean milk. If we can get a certified milk from a laboratory we are doing a wise thing. We can also give to the poor prepared milk with great benefit, but with an intelligent mother handling milk that is delivered cool from the dairy and kept clean at home we may also get excellent results. In reducing the bacteria to the minimum Dr. Hess's method is a very good one.

Dr. Frank W. Pinneo, Newark, N. J.: Clean milk would obviate the necessity for discarding any part of it. The investigations of Dr. Hess are interesting and commendable, but as we can not remove all the bacteria with the upper two ounces of cream why not strive for a still better product—initially clean milk. In Essex County, N. J.—the cradle of certified milk—we have such a product, and where you can have milk that is so nearly free from bacteria (even in the upper two ounces) it will not be necessary to employ the method of Dr. Hess.

Dr. J. J. Thomas, Cleveland: Does Dr. Hess consider the germs themselves as a cause of the summer diarrheas? If so, the removal of the germs by this method would answer the purpose, but, according to recent investigations by Czerny, the summer diarrheas are caused by the acids produced by bacteria acting on the fat or sugar. In that case the harm has already been done and the removal of the upper layer of cream will have no effect at all. It is time for us to wake up to the point of proving or disproving that the condition is due to the germs. The thing of greatest importance is to keep out the germs, but it is a question in many cases of doing the best we can with poor milk. It seems to me that when the laboratory milk is of doubtful quality and we have certified milk, it is better to discard the laboratory milk and to depend on the certified milk. Owing to the pressure brought to bear in Cleveland, certified milk is now being used in modifications, but Cleveland is only one of the two cities in the country where this is done.

Dr. Alfred F. Hess, New York: No doubt it would be better if all the children and infants of the poor could get their milk from laboratories, but I know that in New York most of the babies treated in the dispensary do not get their milk from the laboratory, but are given loose milk, or bottle milk. If we could induce these people to get it from the philanthropic institutions it would be better, but they do not get it there and so we must deal with conditions as we find them. These counts were made from ordinary 8 cent bottle milk, the ordinary cheap milk. I ordered analyses to be made so that I would know just how much to use in order to get a 7 per cent., 10 per cent., and 12 per cent. cream. I do not think Dr. Pinneo quotes the German authors quite correctly in the statement that all the trouble is due to the fat. I believe they admit that there is also some trouble due to the bacteria. There is no reason why this middle milk should not be pasteurized afterward, one will have fewer dead bacteria. Whether the bacteria do harm or whether only the chemical qualities do harm, we know that tubercle bacilli do harm and that the typhoid bacilli do harm and these two germs are found largely in the upper milk, and if we could avoid these we could avoid many cases of illness.

---

[2] Since this article was written, a review of this subject by Dr. John F. Anderson, entitled "The Relative Proportion of Bacteria in Top Milk and Bottom Milk and its Bearing on Infant-Feeding" has appeared in the Journal of Infectious Diseases. I was pleased to find after the lapse of a year a complete confirmation of my laboratory experiments, as these investigations are the structure on which I base the desirability of using middle milk. Dr. Anderson also believes that question is of importance in infant feeding and concludes that "the preponderance of bacteria in top milk may explain why infants sometimes do not thrive on milk made from top milk."

THE ETIOLOGY AND TREATMENT OF THE SO-CALLED SUMMER DIARRHEA IN INFANTS *

C. G. GRULEE, A.M., M.D.
Instructor in Pediatrics, Rush Medical College; Pediatrician to Provident and St. Bernard's Hotel Dieu Hospitals
CHICAGO

Six or seven years ago there were carried out under the supervision of the Rockefeller Institute extensive bacteriologic examinations of the stools of infants suffering from summer diarrhea, with especial regard to the presence of the *B. dysentericus*.[1] Not only the Rockefeller Institute, but many hospitals and laboratories undertook at the same time the same careful research. The results of these researches seemed at first to throw some light on the etiology of this affection. Not only was the *B. dysentericus* (usually of the Flexner type) found frequently, but in some of the cases agglutinins were found in the blood. Soon after these researches in the east, Weaver[2] published a series of examinations by which he was able to show that the dysentery bacillus was to be found in the stools of infants suffering with summer diarrhea in only 25 per cent. of the cases. About the same time Dr. J. S. Welch and myself[3] examined the stools of 17 children with diarrhea in Cook County Hospital, with the result that only one case showed the Flexner bacillus; but we were able to isolate other bacilli, which with the variations from the Shiga-Flexner type recorded by other observers served as links in a chain connecting the *B. coli communis* to the *B. dysentericus*. We came to the conclusion that true dysentery, if such existed in infants, was a relatively rare disease in Chicago.

There are many reasons for believing that *B. dysentericus* is not etiologically connected with a large percentage of the diarrheas in infants. In the first place, the cases which showed the dysentery bacillus in the stools differed clinically in no way from those cases in which no dysentery bacilli were found. In the second place, the dysentery bacilli were usually few in number and extremely hard to find. In the third place, agglutinins were by no means constantly present and, so far as could be ascertained, the antidysenteric serum which has excellent results in the true dysentery in the adult as found, for instance, in Japan, seemed to have no effect whatever on the condition of the infants affected. The dysentery bacillus has never been cultivated from the blood of these infants nor has it ever been found outside the human body (except in the laboratory animals).

I think it is safe to say that unless more certain proof is brought that the *B. dysentericus* is etiologically connected with summer diarrhea we may regard it as at least an open question with the burden of proof resting with those who support the theory, for such it is.

Escherich[4] and very recently Jehle[5] have described a streptococcus enteritis with a definite clinical history and the presence of such complications as nephritis, peritonitis, etc. Jehle regards a given case of diarrhea as due to the streptococcus when that organism is found in great numbers in the stools at the very onset of the attack. Evidently the condition is a streptococcemia with the intestinal canal as its point of entrance.

Escherich[6] has described a so-called epidemic of gastroenteritis occurring in a home for nurslings in which the *B. acidophilus* was found in the stools, and Finkelstein[7] one in which the *Bacillus enteritidis* was found. That there was any connection etiologically between the *B. acidophilus* and the diarrhea was not definitely proved. Cooley,[8] of Detroit, has recently described an epidemic in which the *B. pyocyaneus* was found in the stools.

Many years ago Escherich[9] advanced the theory that the *B. coli communis* suddenly became more virulent and either affected the gastrointestinal canal itself or produced toxins which caused the disturbance. Vaughan[10] is the only one who has been able to produce a toxin from the colon bacillus, and his conditions varied so greatly from those which we encounter in the infant that it is fair to assume that no such toxins are formed by the colon bacillus in the intestinal tract of the infant.

If we stop to consider the clinical picture which the ordinary summer diarrhea presents, we will see that there are present many things which are not compatible with the theory that this is due to infection of the intestinal wall. Usually, although the onset apparently is very sudden, still if we inquire more closely we will find that there have been present for days, weeks and even months, symptoms which point more or less directly to derangement of the gastrointestinal functions and the normal metabolism of the child. Why should we resort to infection to explain a condition which is more easily explained by a graver dietetic error of the same sort or a continuation of the same error past the point of tolerance? But the onset is not so significant as the course. If we take all food from a child having an acute attack of summer diarrhea and give in its place only water, perhaps sweetened with saccharin (not sugar), and containing a little barley or tea, in from 24 to 48 hours the temperature returns to normal, or almost normal, and the child's general condition becomes very much better, so much better, in fact, that the mother frequently regards it as well. To me it is not conceivable that the infection of such a long tube as the intestinal canal could be so readily and easily removed.

At present it seems to me that the infectious nature of summer diarrhea has not been proved: in fact, quite the contrary, and that we must look elsewhere for a satisfactory explanation of conditions as we find them.

Within the past year Finkelstein[11] has described a disorder of nutrition which he designates "metabolic intoxication." The symptoms of this affection are the same as those of summer diarrhea as we commonly encounter it. Finkelstein has proved that this entity is an intoxication metabolic in nature caused primarily by the inability of the organism to assimilate the sugar properly, a condition to which too much fat in the food predisposes. He has proved that after a hunger diet the pure casein of cow's milk can be taken care of, and that sugar as well as fat in any appreciable quantities causes return of the symptoms. His argument in favor of this being due to the food is that on removal of food the symptoms of intoxication quickly disappear. In this condition we find a leucocytosis and albumin, sugar (lactose) and casts in the urine. The breathing is deep and rapid. Meyer,[12] who has worked on the metabolism of metabolic intoxication, believes it to be an acidosis. He thinks that the loss of weight for which the diarrhea does not give us sufficient explanation is due to the escape of moisture from the lungs.

Czerny and Keller,[13] while agreeing with Finkelstein to a degree, suggest that we may have a "toxicosis" due to the decomposition of the food by bacteria, either before ingestion or in the gastrointestinal canal. Although offering no proofs, they are inclined to the opinion that the toxic products are acids split off from the sugar or the fat. Like Finkelstein, in no case have they seen any reason to believe that the casein of cow's milk caused any disturbance in these cases. Czerny and Keller state positively that they do not think that there is such a thing as infection of the gastrointestinal wall, except in the various diseases of the new-born, hemorrhagic diseases, sclerema, etc.

If we are to accept the ideas of Finkelstein or of Czerny and Keller, or both, we must answer several questions. The first one of these is: Can we explain all the clinical findings by these theories? The only symptoms about which there would likely be much question are fever and the urinary findings. That fever is not always due to bacteria and their toxins is proved by its presence in such conditions as uremia, a condition marked by a profound disturbance of metabolism.[14] The presence of sugar in the urine indicates at least a disturbance of absorption and probably also of metabolism. As to the presence of albumin and casts, recently we have found them so frequently and in such a variety of diseases that their presence has lost much of its former significance. In nearly any severe disturbance we would not be surprised to find them, and hence any disturbance of metabolism so severe as to allow lactose to pass into the urine would certainly give rise to substances sufficiently irritating to the kidney to account for the presence of albumin and casts in the urine.

The second question is: Can we account for the pathologic findings on these theories? We can divide the pathology into the lesions of the intestinal wall and the lesions of the other organs. The lesion usually encountered in the intestinal wall is congestion; this may be followed by round-cell infiltration and even by ulceration with infection of the lymphatic tissue. The presence of toxins, whether metabolic or alimentary in origin, would be sufficient to cause a congestion, and if more irritating an infiltration. We have so long been accustomed to regard bacteria as the cause of intestinal ulceration that we have forgotten that when we speak of bacteria acting in this way we mean their toxins. That chemical poisons produced in the body, whether by disturbance of metabolism and excretion through the intestinal wall or by the decomposition of the food, can cause ulcer formation in the intestine, would seem more than probable. Any involvement of the lymphatic tissue must be regarded as due to secondary bacterial invasion. The finding of bacteria in the epithelial cells of the intestinal tract is of little significance, since even a half-hour after death they are often found in cases in which no pathologic condition of the intestine is evident. That they should be found in the epithelial cells of the feces is not to be wondered at, for these in most cases have become detached much earlier than one-half hour previous to defecation.

The only organ outside the intestinal tract involved in most cases is the liver. One of the chief functions of the liver is to arrest poisons on their way to the general circulation. In a condition such as this, in which poisons are present in large amounts, we would expect to find the liver swollen and showing some degeneration of the cells. This, in fact, is the condition in which we find this organ. But some one may ask if this condition is metabolic in nature why does it occur more frequently in summer? To answer this question we must take into consideration three facts: first, in proportion to its weight the skin surface of the infant is much greater than that of the adult; second, a small baby is usually much too warmly clothed, and third, in the hot weather less food is required than in colder months. The first fact shows that the child is more susceptible to heat because of a relatively greater body surface. In addition, the warm clothing prevents the proper excretion through the skin. A mother practically never thinks that a child should have less food during hot weather, and hence the child is kept on the same high diet. The result is that a disturbance of metabolism occurs because of excessive food supply and defective excretion through the skin. On the other hand, if we agree with Czerny and Keller, the whole can be explained by a decomposition of the milk, a thing which is certainly most apt to occur in the summer months.

When, therefore, we stop to consider the question of the etiology of summer diarrhea, we come to the conclusion that, though infection of the intestinal wall probably takes place in some cases, it is not the usual cause of a summer diarrhea in infants, but that this affection is, as a rule, due to a disturbance of metabolism or decomposition of the food.

Having arrived at this conclusion, we can now intelligently turn to the treatment. If we are dealing with a condition which directly or indirectly is due to the food ingested, the first indication is to stop all food. But this is not sufficient. Meyer has shown that in the acute attack the loss of weight, which at times is relatively very great, is due to the loss of fluid in the form of watery solution of the body salts. This takes place primarily from the intestine in the form of diarrhea, but the amount lost in this way will not account for the total loss. Meyer suggests that in all probability the loss takes place in large part through the lungs and that this excretion is evidenced through the rapid deep breathing. Be this as it may, the indication is present for the supply of fluid to the system. This we accomplish by giving barley water or weak tea. However, it is occasionally impossible to give these fluids by mouth because of the comatose condition or extreme asthenia of the patient, and, since it is imperative that fluid be given to these babies, at times it is well to resort to a continuous enema, or even to subcutaneous administration of normal salt solution.

[12] Jahrb. f. Kinderh., 1907, lxv, 585.

[13] Des Kindes Ernährung, Ernährungsstörungen und Ernährungstherapie. Leipzig. u. Wein., 1909, ii, 134.

[14] Since this paper was written Rosenstern has published some interesting experiments in which he shows that giving even a 1 per cent. sodium chlorid solution to a child suffering from a nutritional disturbance will not only raise the temperature but cause a leucocytosis. Monatschr. f. Kinderh., 1909, viii, 9-23.

The starvation diet is continued for from 24 to 48 hours. At the end of this time all symptoms have usually disappeared; even if they have not, nothing can be accomplished by a continuance of this treatment, and food in some form should be administered. For the past two years, I have used skimmed milk as the first food to be given these children and have never had cause to regret my action. I have usually brought this to a boil before giving it, because in this condition it seems to be more readily digested. This kills any bacteria which might act on the milk sugar and which are present in skimmed milk in large quantities. The skimmed milk is given to the amount of from 1¼ to 1½ ounces to the pound weight of the child in 24 hours, and diluted so as to afford enough in quantity to each feeding. The food is sweetened with saccharin when necessary and given at four-hour intervals. This, of course, is a temporary measure and as rapidly as possible milk sugar should be added and the skimmed milk replaced with whole milk. In this no rule can guide us except the condition of the child, and hence the gradual resumption of sufficient food must depend on the judgment of the physician. As a rule, we must be very cautious or there will be a return of the affection. In this method of treating this intoxication one of the most annoying features is the tendency to constipation when the skimmed milk is being replaced with whole milk. At this time the addition of malt to the food frequently brings relief.

Some symptoms may prove troublesome. The vomiting often ceases after the starvation period, especially if a four-hour interval is strictly observed. Sometimes it is necessary to take more active measures, such as stomach washing. The use of such medicaments as bismuth, it seems to me, is limited to such cases as do not respond to the other forms of treatment, and they are not common. The diarrhea will nearly always take care of itself. I sometimes employ colonic flushings, but more with the idea of reducing the temperature than of cleaning out the bowel. The reduction of the temperature can be accomplished usually by the measures previously suggested, but hydrotherapy is often of great advantage and when delirium is present antipyrin acts very favorably, not only in controlling the delirium, but also in reducing the temperature. Another distressing feature is distention. This is present usually only in the more protracted cases and is due to a circulatory disturbance of the intestine whose exact mode of action we do not know. For the temporary relief of this condition the introduction of a tube into the rectum, the other end of which is placed in a vessel containing warm water, frequently brings relief. We may also use colonic flushings and hot external applications to the abdomen even in the form of turpentine stupes. Collapse can best be combated by mustard packs followed by saline infusion or continuous saline enema.

I have purposely made no mention of the use of calomel or intestinal antiseptics. I have always felt that if we can obtain results in these infants without the use of drugs it is well to do so, and the treatment outlined will do what we desire. I feel that the use of calomel has been very much abused. It is conceivable that by further irritating an already irritated bowel it may do distinct harm and its qualities as an intestinal antiseptic are minimum. As to intestinal antiseptics in general, I can not see that their use is in any way indicated.

Clinical Notes

CALCIUM SALTS IN THE TREATMENT OF EPILEPSY

WITH REPORT OF THE FIRST CASE

A. P. OHLMACHER, M.D.
DETROIT

With a large experience in the study and treatment of epilepsy, such as was afforded by my seven years' sojourn in the laboratory and wards of the Ohio Hospital for Epileptics, it is natural that I should be most conservative in expressing an opinion in favor of a new method of treating this malady. More particularly should I be reluctant about mentioning the seemingly favorable results that accrued with but a small number of cases. It was considerations of this nature that restrained me from putting on record the really extraordinary success that followed my first trial of the remedial effect of a calcium salt in epilepsy, and my avowed policy of postponement for further and more extensive corroboration of that success would not now be broken except for the appearance of an article from a physician in asylum practice,[1] who reports what he believes to be the first instance in which calcium lactate has been used for treating epilepsy. Alike to supplement the favorable record published by Dr. Littlejohn, who shows by tabular exhibits the suppression in two patients of epileptic attacks on the administration of calcium lactate over a period of three or four months, and to claim such credit as may be due from the standpoint of originality and historic priority, I herewith present a narrative of the first case of epilepsy in which I employed a calcium salt, together with the events and experiments which led me to the trial of this particular medication.

HISTORY OF CASE

Patient.—W. T. H., was brought to me for treatment in April, 1906, when he was 4 years and 4 months old.

Family History.—The child's parents were living and in good health; an older brother and a younger sister were free from neurotic disease. There was no record of epilepsy in the family, which, on the mother's side, was prominent in social and financial circles. The father was a well-educated, retired physician.

Personal History.—As an infant the patient was remarkable for his uneventful progress and perfect physical and mental development, which was the particular pride of a well-known pediatrist who supervised this period. A month after his third birthday the first manifestation of nervous disorder was noticed, and after a series of consultations between several general physicians and specialists a diagnosis of *petit mal* was reached and treatment with sodium bromid instituted. Occasional *petit mal* followed, and eight months after the first attack the primary severe *grand mal* occurred.

Frequency of Attacks.—By January, 1906, the epileptic seizures had become fully established, and the nurse, who gave unremitting care to the child, recorded the number and classified them as "light," "hard," and "convulsions," by which were meant *petit mal* (momentary loss of consciousness without fall), *petit mal* (with fall but no marked convulsions), and *grand mal* with all the events of a particularly severe major epileptic attack. In January there was a total of 844 attacks—401 "light," 424 "hard," and 19 "convulsions." For the following months to the time I finally had withdrawn the bromid by gradual reduction the total monthly number of attacks varied from 530 to 1,012, the ratio of the three varieties being about as above indicated. Following the withdrawal of the bromid the usual change from numerous light to fewer severe attacks took place as shown by a monthly total of 35 to 118, and of these *grand mal* seizures numbered 34 to 73 a month. June 3, 1907, the treatment under special consideration was begun, and the record shows 18 attacks, all *grand mal*, for this month, none for July, 72 *grand mal* in August, 6 in September, and from Sept. 7, 1907, to the present writing, June 30, 1909, *no further epileptic attacks.*

---

[1] Littlejohn, A. R.: Calcium Lactate in the Treatment of Epilepsy, The Lancet, May 15, 1909, p. 1382.

Mental Condition.—The normal mental growth at the outset of the epilepsy ceased abruptly, and retrogression began which, when I first saw the patient, had reached the stage of a low-grade epileptic imbecility. After the bromid was stopped the hoped-for mental improvement did not follow, and it was not until after all attacks had ceased with the inauguration of the new treatment that a gradual clearing of the mind was observed, and this unclouding is still going forward to a degre most striking after the apparently hopeless state that once existed. In fact, the child seems to have suffered a mental non-existence for the two years and eight months of the epilepsy, and, with the suppression of the neurosis, to have resumed his mental growth from the time when the attacks began.

Previous Treatment.—The child was placed in the hands of good physicians, to whose aid was brought the advice of several noted specialists from two of our largest metropolitan centers. Aside from such general dietetic and hygienic precautions as are usually advised, bromids were employed, and with the increasing number of seizures, pushed in dosage. An operation on the cranium based on the theory of localized pressure was at one time considered but not undertaken.

Personal Treatment.—When I assumed charge of the case my announced plan was to attempt the withdrawal of bromids and to correct any possible source of reflex irritation. In the course of an examination of the digestive apparatus by a well-known gastroenterologist subnitrate of bismuth was administered preliminary to a skiagraph, and with an apparent reduction in the number of attacks following it, this drug was employed for some months without benefit. Finding that no special attention had been paid to the eyes, I advised the services of an expert refractionist, who found evidence of refractive anomaly and instituted treatment first by atropin-relaxation of the accommodation for a period, after which the compound hyperopic astigmatism was corrected. It was at the same time that the reduction of bromid had reached the end, and the resulting change from very numerous *petit mal* to a lessened total, but an increased number of *grand mal* followed. Some of the *grand mal* now came in series, never, however, reaching a full *status epilepticus.* I was with the patient during one of these series and witnessed *grand mal* as severe as any that had ever come under my notice in a large institutional experience.

Special Treatment.—Such was the condition of the patient when he came to Detroit for another of the several periods to allow of my personal observation. During March, April and May the lad had frequent nose-bleed following the *grand mal* cycles, and the nurse claimed she could detect the odor of blood on the breath during a convulsion and prior to the onset of the visible hemorrhage. I was at this time actively engaged in the practice of therapeutic immunization where the problem of blood coagulability presented itself, and I had employed Wright's method of measuring the time of blood coagulation, as well as his plan of using calcium salts to fortify a defective coagulability. Accordingly, when my attention was arrested by the reports about the epistaxis, I made the first blood-clotting test June 2, 1907, finding that the patient's blood failed to clot in 4 minutes, while a control blood under the same conditions firmly coagulated in 1½ minutes. The following day I began the administration of calcium lactate in doses of 7 to 10 grains dissolved in hot water and added to milk, three times a day. This medication has been continued with no change except occasionally reducing to one or two doses daily, to the present time. There has been no evidence of a harmful effect from the drug during this prolonged administration. Under its influence the blood-clotting time reached 2½ minutes by June 19, 1¾ minutes by July 6, and on numerous tests since, I have not found it to exceed 2 minutes, though rarely attaining the normal minimum of 1½ minutes. Since the cessation of the epilepsy three months after commencing the calcium lactate the child had occasional nasal hemorrhages, apparently related to periods of lowered coagulability not entirely brought to normal by the calcium salt. No lesion or abnormality has been found in the nose to explain the epistaxis.

RATIONALE OF TREATMENT

It was solely on the indication afforded by the hemorrhagic tendency in my first patient that I was led, after verifying by laboratory tests a tardy blood coagulability, to use the calcium salts in epilepsy, with the happy result just described. At the time I administered it MacCallum's observations on calcium metabolism as related to parathyroid intoxication and to tetany had not been published, nor had Carle's paper appeared on calcium chlorid in therapeutics,[2] with its recommendation for the use of the drug to allay nervous irritability in tetany, laryngismus stridulus, and "convulsions."

Incomplete observations on several additional cases of epilepsy treated with calcium lactate tend to confirm the favorable results obtained with my first case, and now that Littlejohn[1] has recorded the beneficial outcome in his early tests I shall be encouraged to prosecute further therapeutic experiments, for which I hope to have the opportunity through the courtesy of the authorities of the Ohio Hospital for Epileptics.

DERMATITIS FROM HAIR DYE

ANOTHER CASE OF POISONING FROM MRS. POTTER'S WALNUT JUICE HAIR STAIN

JOHN G. BURKE, M.D.
PITTSBURG, PA.

History.—On June 23, 1909, I was called to see a woman who gave a history of having an eruption on the face which first appeared four weeks previously, subsided somewhat in two weeks and then recurred. The burning and itching were so intense that the patient could not sleep and nothing prescribed by the two physicians who had her in charge gave her any relief.

Examination.—Her face, neck and part of her shoulders were red and swollen and the area involved covered by numerous minute vesicles all in the same stage of development. While observing the patient I noticed that she had a habit of placing the palms of both hands on her hair and then pulling them down over her face. This suggested the possibility of the irritant being a hair-lotion or dye. Questioning her along this line, I elicited the information that she had been using "Mrs. Potter's Walnut Juice Hair Stain," having made two applications—the first one shortly before the first appearance of the eruption, and the second application two weeks later, as it was not suspected that the hair stain had anything to do with the eruption.

Diagnosis.—This history convinced me that the trouble was a dermatitis due to the use of the hair stain, as I had read the reports of the other cases published in THE JOURNAL.[1]

Treatment.—I advised her to keep her hands off her hair and prescribed the liquor alumini acetatis, N.F., diluted one to three with water, applied on compresses, which gave her immediate relief. The itching stopped and the swelling subsided so that three days later her face appeared normal except for a slight desquamation.

---

2. Jour. de Méd. de Bordeaux, 1907, xxxvii, 472.

3. This makes the fifth case recorded in THE JOURNAL. The other cases appeared in the issues of Feb. 13, 1909; March 6, 1909, and two in the issue of April 3, 1909.

As this stain evidently has a large sale, as it is extensively advertised in the magazines and daily papers, cases of dermatitis from its use must be more frequent than the cases reported show. One fact that is liable to mislead the physician is that on account of the scalp being less sensitive to irritants than the skin of the face the scalp is not involved and the connection between an eruption on the face and the application of a dye to the hair is overlooked. The use of hair dyes and face lotions is becoming so common that we must consider them as possible causative factors in any eruption about the face, neck and scalp that we can not class as one of the recognized diseases.

632 Fulton Building.

AN EPIDEMIC OF EMPYEMA

E. H. MUSSON, M.D.
NORBORNE, MO.

The following experience seems sufficiently remarkable to be worth reporting. The cases mentioned all occurred in my practice during the six months from Dec. 1, 1908, to June 1, 1909, in a rural community having a radius of less than four miles, with the center about seven miles northwest of Norborne, Mo.

I attended in this community six cases of frank lobar pneumonia and eight cases which I diagnosed pleuropneumonia. These latter failed to show clear physical signs of consolidation, the clinical picture being that of a severe pleuritis. All but one, an infant, however, raised a small amount of slightly "rusty" sputum. One of the pneumonia patients and six of the pleuropneumonia patients developed empyema as a sequel. Another pleuropneumonia patient had a large serous effusion, making eight cases of effusion out of the fourteen, seven being purulent and one non-purulent.

The treatment of most of the cases preceding effusion was simple, consisting of good nursing, elimination, very hot applications to the chest for pain, with morphin given in a few instances, and tepid bathing for combating a dangerously high temperature.

The empyema patients ranged from 14 months to 72 years of age. Five were males and two females. In four cases the pus was in the right pleural cavity and in three in the left. I operated twice by incision in an intercostal space and five times by resection of a rib, and all recovered. The gross appearance of the pus was that of a pneumococcus infection. In the case of non-purulent effusion the patient recovered satisfactorily after the withdrawal of nearly a half-gallon of fluid from the pleural cavity.

THE ASSOCIATION OF ENTEROCOLITIS WITH PNEUMONIA

MARK LIEBERT, M.D.
BROOKLYN

The prevailing epidemic of enterocolitis and pneumonia running typical courses side by side will, no doubt, arouse the interest of many practitioners. The field for bacteriologic study should yield much useful information. The two diseases apparently aggravate each other, but the course of either is not otherwise modified. They appear either to arise simultaneously or closely to follow each other. The diarrhea follows the operation of the usual causes, most often occurring in bottle-fed infants or children fed on malted milk, though I have seen a case in an exclusively breast-fed infant.

The simultaneous involvement of the respiratory and gastrointestinal tracts would suggest the presence of a common predisposing cause. In a few cases there was a history of a preceding prolonged bronchitis. The stools are small in amount and occur at great frequency. At first they are greenish, mucoid and very fetid; later they become serous in character. They may be yellowish, showing particles of curdled undigested milk. In one of my cases the stools were blood-streaked. If diarrhea exists before consolidation has taken place in the lungs, there is usually a temperature between 101 F. and 102 F. With consolidation the temperature may be very high, reaching 105.5 F. Prostration is marked. In one of my cases cough was entirely absent, while the lungs gave typical physical signs. These cases usually occur in the second year, although I had one case in a boy of six.

Treatment should be directed chiefly to the diarrhea. In this I follow the teachings of Dr. Joseph E. Winters, of New York. Castor oil at the outset, starvation for from 24 to 36 hours, with plenty of cold water during this period. I have seen fever go down precipitately under this treatment alone. Even drugs are to be excluded. At the end of from 24 to 36 hours feeding is begun according to age. For children less than 10 months old, cow's milk is modified so as to minimize proteids; above 10 months cereals are given and milk avoided. I do not think that the exclusion of milk tends to aggravate the course of the pneumonia. The fever is treated by tepid sponging and the ice-bag to the head. High rectal enemas, as shown by Dr. Winters, may increase the cyanosis and tend to produce collapse.

This is written in the hope that it may interest others whose experience has been extensive in this class of cases. It is a live, timely topic and much may be said that will prove beneficial to all in the treatment of two dangerous affections.

57 Christopher Avenue.

PIN EXTRACTED FROM TRANSVERSE COLON

FRED V. WATSON, M.D.
ANTIGO, WIS.

The cases reported in THE JOURNAL, one (April 10, 1909) of a darning needle, extracted from epigastrium of an infant, the other (June 5, 1909) of a scarf pin swallowed by an infant and found protruding from the anus, have prompted me to report a case that occurred in my practice last week.

History.—A young woman, aged 18, with an acute attack of appendicitis second day complained of a sharp sticking pain over the line dividing the right hypochondriac region from the epigastric region. As there was extreme tenderness over McBurney's point with tympanites, colicky pain and vomiting, pulse 120, temperature 102 F., nothing was thought of this pain, but a diagnosis of acute catarrhal appendicitis was made and immediate operation advised.

Operation.—Under ether anesthesia I made my incision directly over McBurney's point, and on searching for the appendix I picked up a part of the transverse colon that contained a pin. This was extracted and the wound closed with a puckering string of Pagenstecher's linen. The appendix was then located and found to be in an acute catarrhal condition, curled on itself, with adhesions from a former attack. It was removed in the usual manner and the patient made a good recovery. The patient has no knowledge of swallowing the pin.

Therapeutics

TAPEWORM

While the eradication of this unwelcome parasite sounds simple enough when the treatment of the condition is read in a text-book, such treatment, and any treatment, is often not successful in obtaining the head of the animal, which is the main object at which the treatment aims. Administration of the oleoresin of male fern is the treatment most generally used, and perhaps has been the one most frequently successful.

Dr. Seymour Spier, of New Haven, Conn., has had almost constant success with pomegranate. An unpublished letter from this physician thus describes his exact method of procedure: He first prepares a decoction from 60 grams of fresh pomegranate bark to 500 c.c. of water, slowly boiling this down to 250 c.c. (2 ounces of the bark to a pint of water, boiled down to half a pint). On the day before the administration of the anthelmintic the patient is given a cathartic, a good dose of compound licorice powder or other efficient purgative, in the morning. He is allowed breakfast and noon meal as usual. The supper, or evening meal, should consist of bread, or crackers, in milk. Before retiring he is given a soap suds enema, and at 6 a. m. the next morning, the morning of treatment, he is given half, viz., 125 c.c. (4 ounces) of the half-pint of the prepared pomegranate decoction. Half an hour later he is given a tablespoonful of castor oil, and in another half hour the patient takes the remainder (125 c.c., or 4 ounces) of the decoction. In thirty minutes this is followed by two tablespoonfuls of castor oil. The oil may be given in lemon juice on cracked ice, or on black coffee. If the oil is positively objectionable, instead of it, forty-five minutes after the administration of the last dose of pomegranate decoction he may be given a dose of salts, or even a bottle of the pleasant tasting effervescing citrate of magnesium. In a few hours the patient almost invariably passes the worm, as a whole with head attached, without any prolonged griping or very frequent movements. The patient is then immediately ready for his breakfast or luncheon.

If previous examination of the segments of the worm has shown it to be of the pork variety (*Tænia solium*), Spier adds one drop of croton oil to the last portion of the decoction.

As the above decoction is bitter, and sometimes nauseating to the patient, and as a concentrated preparation of the alkaloids of the pomegranate is made especially for the treatment of tapeworm, and can be obtained, it may be ordered. It is much pleasanter to take and as effective as the crude drug. In fact, Spier says he has found it difficult to obtain fresh, active pomegranate bark, and to be successful the drug must be active.

The only disagreeable symptoms that occur from the administration of pomegranate in the above dosage is that there may be dizziness, and sometimes a partial amblyopia, which lasts from five to fifteen minutes. This is never serious, soon passes off, and is generally dispelled by a dose of whiskey or brandy.

Pomegranate (Granatum, U. S. P.) occurs as a bark which contains, besides about 25 per cent. tannic acid, several alkaloids, the most important of which are pelletierin and isopelletierin (sometimes called isopunicin). These alkaloids have some action similar to atropin, hence probably the effect on the eyes. If toxic doses be administered, or if large doses remain long in the gastrointestinal canal without being pushed rapidly along by cathartics, not only would dizziness and amblyopia be caused, but there would be bowel cramps, nausea, vomiting, and there might be muscle cramps, especially in the legs.

If the alkaloids be carefully prepared, the official preparation of pelletierinæ tannas, which is a mixture of the alkaloids of the pomegranate, should be an efficient preparation. The dose listed in the Pharmacopeia is 0.25 gram (4 grains).

Dr. Spier has never seen serious or persistent unpleasant symptoms occur from the administration of pomegranate as he has described it.

New and Nonofficial Remedies

SINCE THE PUBLICATION OF THE BOOK "NEW AND NONOFFICIAL REMEDIES, 1909," THE FOLLOWING ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK ARE ASKED FOR.

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

(Continued from page 460)

CEPHAELINE—Cephaelina.—An alkaloid, $C_{14}H_{20}NO_2$, obtained from ipecacuanha root.

Cephaelin occurs as snow-white, fine, interlacing needles which readily turn yellow. It is soluble in ether and caustic soda solutions, melts at 96°-102° C (204.8°-215.6° F) and turns brown when heated to 120° C (248° F). With Fröhde's reagent, a freshly prepared solution of 0.1 Gm. sodium molybdate in 10 Cc. concentrated sulphuric acid, it gives a purple color which hydrochloric acid changes to prussian blue.

Action and Uses.—These are identical with those of ipecac. It is relatively more emetic and less nauseant and causes relatively more renal irritation and less cardiac depression. It may be employed as an emetic and expectorant.

Dosage.—0.005 to 0.01 Gm. (1/12 to 1/6 grain) in pills or as a powder triturated with sugar of milk. The hydrochloride is soluble.

HOLADIN AND BILE SALTS, Fairchild.—This preparation is a mixture of Holadin (which see) 5 parts with bile salts, Fairchild (which see) 1 part, put up in 3 grain capsules, containing holadin approximately 0.15 Gm. (2½ grains), and bile salts 0.03 Gm. (½ grain).

Dosage.—One capsule about three hours after meals and one capsule at bedtime.

Prepared by Fairchild Bros. & Foster, New York.

NOVOCAINE NITRATE—Novocainæ Nitras.—Novocaine nitrate, $C_6H_4.NH_2(COO.C_2H_4.N(C_2H_5)_2.HNO_3 = C_{13}H_{21}O_5N_3$, is the nitrate of p—aminobenzoyldiethylaminoethanol, the base contained in novocaine.

Novocaine nitrate occurs in small colorless and odorless crystals, soluble in water and alcohol. The aqueous solution is neutral in reaction. Melting point 100°-102° C. (212°-215° F.).

If 0.1 Gm. novocaine nitrate be dissolved in 1 Cc. concentrated sulphuric acid and a solution of ferrous sulphate carefully floated above it, a brown zone is formed at the surface of contact of the two solutions. 1 part novocaine nitrate dissolved in 10 parts water and acidified with nitric acid, should yield no precipitate upon the addition of silver nitrate solution.

Actions and Uses.—As for novocaine; may be prescribed in combination with silver salts, with which it forms no precipitate.

Dosage.—Used in 3 per cent. solutions.

Manufactured by Farbewerke vorm Meister, Lucius & Bruening, Hoechst A. M. (Victor Koechl & Co., New York).

Patents or trademarks: None.

MEDICAL COLLEGES OF THE UNITED STATES

Below are given brief descriptions of the medical colleges in the United States that are legally chartered to teach medicine, several of which do not grant degrees. The name, address, year of organization, history and date when first class graduated is given in each instance. Unless otherwise stated, a class graduated each subsequent year. Where official reports have been received from the college, information regarding faculty, entrance requirements, length of term, fees, students, graduates, name of dean and next session is given without discrimination, regardless as to whether the college is sectarian or not. In the few instances where such reports were not received the information published is from other reliable sources. Extracts of rules and the membership of each of the college associations is shown following the list of colleges. Figures showing population of cities and states are taken from the United States Census Bureau's estimates for 1906.

ALABAMA

Alabama, population 2,017,877, has two medical colleges, the Medical Department of the University of Alabama and the Birmingham Medical College, located, respectively, in Mobile and Birmingham. The population of Mobile is 42,903 and of Birmingham 45,869.

Birmingham

Birmingham Medical College. Avenue F and Twentieth Street.—Chartered in 1894. The first class graduated in 1895. There are 22 professors and 10 assistants, total 32. The course of instruction embraces four separate sessions of seven months each. The fees are $75 for each of the first three years and $100 for the fourth. The Dean is Dr. B. L. Wyman. Registration, 1908-9, 169, graduates, 28. The sixteenth session begins Sept. 29, 1909, and ends Apr. 28, 1910.

Mobile

Medical Departm [illegible] of Alabama. St. Anthony and Lawrence [illegible] as the Medical College of Alabama. Classes [illegible] and in all subsequent years except 1862 t [illegible] as reorganized as the Medical Department of the University of Alabama in 1897. All property was transferred to the University of Alabama and the present title assumed in 1907. The faculty consists of 8 professors and 17 lecturers and assistants, a total of 25. The course of study covers four years of seven months each. The total fees for each of the first three years is $100; for the fourth year, $125. The Dean is Dr. Rhett Goode. The total registration for 1908-9 was 191, graduates, 29. The forty-fourth session begins Sept. 20, 1909, and ends Apr. 18, 1910.

ARKANSAS

Arkansas, population 1,421,574, has two medical colleges, the Medical Department of the University of Arkansas and the College of Physicians and Surgeons, both located in Little Rock, a city of 39,959 people.

University of Arkansas Medical Department, Second and Sherman Streets.—Organized in 1879 as the Arkansas Industrial University. The first class graduated in 1880. It assumed the present title in 1899. The faculty consists of 19 professors and 13 lecturers and assistants, total 32. The course of study covers four years of seven months each. The fees are: Matriculation, $5, paid but once; tuition, per year, $60; graduation fee, $25. The Secretary is Dr. C. E. Witt. Total registration, 1908-9, was 179; graduates, 22. The fourteenth session begins Oct. 1, 1909, and ends Apr. 30, 1910.

College of Physicians and Surgeons. Lincoln Avenue, north of the Union Station.—It was organized in 1906. The first class graduated in 1907. The faculty consists of 30 professors and 12 lecturers and assistants, a total of 42. The course of study covers four years of seven months each. The Dean is Dr. J. P. Runyan. The total registration for 1908-9 was 81, graduates, 14. The third session begins Oct. 1, 1909, and ends May 1, 1910.

CALIFORNIA

California, population 1,648,049, has seven medical colleges. Four are located in San Francisco, a city having, before the earthquake, 355,919 inhabitants. They are Leland Stanford Junior University College of Medicine, Medical Department of the University of California, Hahnemann Medical College of the Pacific and the College of Physicians and Surgeons. The College of Physicians and Surgeons and the California Eclectic Medical College are situated in Los Angeles, population 116,420. The Oakland College of Medicine and Surgery is in Oakland, population 73,812.

Los Angeles

College of Physicians and Surgeons. 516 E. Washington Street.—It was organized in 1903. The first class graduated in 1905. The course covers four years of nine months each. The faculty consists of 29 professors and 13 lecturers and instructors, a total of 42. The fees for the four years respectively are $135, $132, $107 and $132. The Dean is Dr. Charles W. Bryson, Delta Building, Los Angeles. The registration for 1908-9 was 32, graduates 5. The seventh session begins Sept. 5, 1909, and ends June 15, 1910.

California Eclectic Medical College. 846 Lyon Street.—Organized in 1879 at Oakland as the California Medical College. Removed to San Francisco in 1887. Suspended in 1906. Reorganized at Los Angeles with the present title in 1907. Classes were graduated in 1880, and in all subsequent years except 1907. It has a faculty of 27 professors. The Dean is Dr. J. A. Munk. The registration for 1908-9 was 7; graduates 4. The thirtieth session begins Sept. 13, 1909, and ends May 21, 1910.

Oakland

Oakland College of Medicine and Surgery. Thirty-first and Grove streets.—Organized in 1900, opened in 1902. The first class graduated in 1906. The faculty numbers 33. The course covers four years of nine months each, and the classes are limited to ten students each. The total fees for each of the four years respectively are $165, $160, $150 and $175. The Registrar is Dr. Edward N. Ewer. The total registration for 1908-9 was 17; graduates, 4. The eighth session begins Aug. 15, 1909, and ends about May 21, 1910.

San Francisco

Hahnemann Medical College of the Pacific. Homeopathic. Sacramento and Maple streets.—Organized in 1881 as the Hahnemann Medical College. The first class graduated in 1884. In 1888 it became the Hahnemann Hospital College of San Francisco. It assumed the present name in 1902. It has a faculty of 19 professors and 13 lecturers, instructors, etc., a total of 32. The course covers four years of seven months each. Total fees for the first year are $155, and $100 for each of the other three. The Dean is Dr. James W. Ward, 1380 Sutter Street. The total registration for 1908-9 was 23; graduates 6. The 28th session begins Aug. 31, 1909, and ends Apr. 28, 1910.

College of Physicians and Surgeons. 344 Fourteenth Street. [illegible]. The first class graduated in 1897. The [illegible] The course covers four years of thirty weeks [illegible] is Dr. Winslow Anderson. Registration for 1908-9 was 40; graduates 11. The fourteenth session begins Sept. 14, 1909, and ends May 14, 1910.

San Francisco-Palo Alto

Leland Stanford Junior University, College of Medicine. University Campus, Palo Alto, and Sacramento and Webster Streets, San [illegible] 1858 as the Medical Department of the [illegible] Discontinued in 1864. Revived in 187 [illegible] College of the Pacific, Medical Department of the University College of San Francisco in 1873. Became Cooper Medical College in 1882. United with Leland Stanford Junior University with present title in 1908. Classes were graduated in 1860, and in all subsequent years, except 1865 to 1869, inclusive. Three years of collegiate work are required for admission. The work of the first three semesters will be given at Palo Alto, the last five semesters at San Francisco. The faculty consists of 18 professors and 36 lecturers, instructors, etc., 54 in all. The course covers four years of eight and a half months each. Fees: First year, $175; second and third years, $170 each; fourth year, $195. The secretary is Dr. William Fitch Cheney. Total registration for 1908-9 was 117; graduates, 22. The forty-first session begins Aug. 15, 1909, and ends May 7, 1910.

San Francisco-Berkeley-Los Angeles

University of California, Medical Department. University Campus, Berkeley; Second and Parnassus Avenues, San Francisco and Buena Vista and Alpine Streets, Los Angeles.—Organized in 1863 as the Toland Medical College. The first class graduated in 1865. In 1872 it became the Medical Department of the University of California. In 1909 it absorbed the College of Medicine of the University of Southern California, which became a clinical department at Los Angeles. Two years of collegiate work are required for admission. At the San Francisco Department only the last two or clinical years are taught, the first two being at Berkeley. At the Los Angeles Department during the session of 1909-10 the work of the last three years will be taught, but beginning with the session of 1910-11 and thereafter all the work of the first two years will be at Berkeley and the work of the last two years at either Los Angeles or San Francisco. The faculty is composed of 43 professors and 80 associates and assistants, a total of 123. The course covers four years of nine months each. The fees are: Matriculation, $5; tuition, $150 each year; laboratory fees extra. The Dean at San Francisco is Dr. Arnold A. D'Ancona; at Los Angeles, Dr. W. Jarvis Barlow. Total registration of the two schools for 1908-9 was 108; graduates, 23. The thirty-seventh session begins Aug. 15, 1909, and ends May 11, 1910.

COLORADO

Colorado, with a population of 615,570, has three medical colleges. Two of these, Denver and Gross College of Medicine and the Denver College of Physicians and Surgeons, are in Denver, which has a population of 151,920, the other, the Colorado School of Medicine, is at Boulder, population 12,000.

Boulder

University of Colorado School of Medicine.—Organized in 1883. Classes were graduated in 1885 and in all subsequent years, except 1898 and 1899. The faculty embraces 25 professors and 22 lecturers and assistants, a total of 47. The work embraces a graded course of four years of nine months each. Beginning with the session of 1910-11 the entrance requirements will be two years of college work counting toward a degree in arts in an accredited college or university. The tuition is $52 per year; there are no other fees. The Dean is Dr. William P. Harlow. The total registration for 1908-9 was 54; graduates, 11. The twenty-eighth session begins Sept. 13, 1909, and ends June 8, 1910.

Denver

The Denver and Gross College of Medicine, 1025 Fourteenth Street.—It is the Medical Department of the University of Denver. Organized in 1902 by the union of the Gross Medical College (organized in 1887) with the Denver College of Medicine (organized in 1880). Classes were graduated in 1903 and in all subsequent years. The faculty is made up of 33 professors, 38 assistants and instructors, a total of 71. The course covers four years of eight months. Fees for each of the four years respectively are $130, $130, $131 and $126. The Dean is Dr. George H. Stover, 1443 Glenarm Pl. The total registration for 1908-9 was 109; graduates, 23. The twenty-eighth session begins Sept. 28, 1909, and ends May 26, 1910.

Denver College of Physicians and Surgeons (Regular and Homeopathic), 1317 Fourteenth Street.—Organized in 1894 as the Denver Homeopathic College. The name was changed in 1907 to the Westminster University College of Medicine and again in 1908 to the present title. Since 1907 it has offered to teach two systems of medicine. Its faculty numbers 46. The Dean is Dr. David A. Strickler. The total registration for 1908-9 was 34; graduates, 7. Next session begins Sept. 6, 1909, and ends May 12, 1910.

CONNECTICUT

Connecticut, with a population of 1,005,716, has only one medical college, located in New Haven, population 121,227.

New Haven

Yale Medical School, York and Chapel Streets.—This is the Department of Medicine of Yale University. In 1810 a charter was granted for the establishment of this school, and in 1813 it was organized as the Medical Institution of Yale College. The first class graduated in 1814. The faculty consists of 14 professors and 50 lecturers and assistants, a total of 64. The requirements for admission are two full years of collegiate work of fifteen hours per week. The course covers four years of nine months each. The fees are $150 each year; in the first year there are additional fees amounting to $18, and in the second $8, and there is a graduation fee of $10. The Dean is Dr. Herbert E. Smith, New Haven. The total registration for 1908-9 was 141; graduates, 15. The ninety-seventh session begins Sept. 30, 1909, and ends June 22, 1910.

DISTRICT OF COLUMBIA

Washington, population 307,716, has three medical colleges; George Washington University Department of Medicine, Georgetown University School of Medicine and Howard University Medical Department.

Washington

George Washington University, Department of Medicine, 1325 H Street, N.-W.—Organized in 1825 as the National Medical College, Medical Department of Columbian College. Classes were graduated in 1826 and in all subsequent years, except 1834 to 1838, and 1861 to 1863, inclusive. The original title was changed to Medical Department of Columbian University in 1873. In 1904, by an act of Congress, it received its present title. The faculty is composed of 42 professors and 40 instructors, demonstrators and assistants, a total of 82. The course covers four years of eight months each. The total fees are $150 per year. The Dean is Dr. William C. Borden. The total registration for 1908-9 was 156; graduates, 33. The eighty-eighth session begins Sept. 29, 1909, and ends June 8, 1910.

Georgetown University, School of Medicine, 920 H Street, N.-W.—Organized in 1851. The first class graduated in 1852. The faculty contains 20 professors, 54 instructors and assistants; total 74. The course of study covers four terms of eight and one-half months each. The fees are $150 each year. The Dean is Dr. George M. Kober, 1600 T Street. The registration for 1908-9 was 89; graduates, 15. The fifty-ninth session begins Oct. 1, 1909, and ends June 11, 1910.

Howard University, Medical Department, Fifth and W Streets, N.-W.—Chartered in 1867. Organized in 1869. The first class graduated in 1871. Colored students compose a majority of those in attendance. The faculty comprises 22 professors and 30 lec- [illegible] in all. The course covers four years of [illegible] es of each session are $100, plus $10 for [illegible] is Dr. William C. McNeill. Registration [illegible] uates, 26. The forty-second session be- [illegible] s June 1, 1910.

GEORGIA

Georgia, population 2,443,719, has five medical colleges; Medical College of Georgia, located in Augusta, population 43,125; Atlanta College of Physicans and Surgeons, Atlanta School of Medicine, the Georgia College of Eclectic Medicine and Surgery, and the Hospital Medical College are in Atlanta, a city of 104,984 population.

Atlanta

Atlanta College of Physicians and Surgeons, Butler and Armstrong [illegible] 1898 by union of the Atlanta Medical Co [illegible] and Southern Medical College, organized i [illegible] graduated in 1899. It has a faculty of 23 professors and 28 assistants, a total of 51. The course of study covers four years of seven months each. Fees: First and second years, $80 each; third and fourth, $100 each. The Dean is Dr. W. S. Elkins, 29 Luckie St. Total registration of students for 1908-9 was 280; graduates, 37. The twelfth session begins Sept. 27, 1909, and ends May 1, 1910.

Atlanta School of Medicine, Luckie, Barton and Cain Streets.—Organized in September, 1905. The first class graduated in 1906. The course covers four years of seven months each. It has a faculty of 13 professors and 27 lecturers and assistants, a total of 40. The fees for each of the first two years are $70; for each of the last two, $80. The Proctor is Dr. Edward G. Jones. The total registration for 1908-9 was 281; graduates, 51. The fifth session begins Oct. 1, 1909, and ends May 1, 1910.

Georgia College of Eclectic Medicine and Surgery, Tanner Street, near Edgewood Avenue.—Organized in 1877 as the Georgia Eclectic Medical College. In 1884 it acquired the charter of the College of American Medicine and Surgery. It assumed its present name in 1886. The first class graduated in 1878. The faculty consists of 14 professors and 6 assistants, a total of 20. Tuition is $80 per year; graduation fee, $25. The Proctor is Dr. E. B. Thomas. Total registration for 1908-9 was 66; graduates, 15. The next session begins Sept. 21, 1909, and ends Apr. 21, 1910.

Hospital Medical College, Eclectic, Capitol Avenue and Richardson Street.—Organized in 1908. The faculty consists of 16 professors, and 8 lecturers and assistants, a total of 24. The tuition fees are $80 each year; graduation fee, $30. The Dean is Dr. William Bernard Lingo. Total registration for 1908-9 was 43; graduates, 17. The next session begins Sept. 15, 1909, and ends April 1, 1910.

Augusta

Medical College of [illegible] Telfair Streets.—Organized in 1828 as the " [illegible] eorgia, the name being changed to the Medical [illegible] 1829. The faculty includes 17 professors and 17 assistants, 34 in all. The course is four years of seven months each. Fees for the four years respectively are $90, $85, $100, $100. The Dean is Dr. Joseph Eve Allen. The total registration for 1908-9 was 99; graduates, 22. The seventy-eighth session begins Oct. 1, 1909, and ends May 1, 1910.

ILLINOIS

Illinois, population 5,418,670, has thirteen medical colleges, four of which are night schools, all located in Chicago, a city of 2,049,185 inhabitants, and are as follows: Rush Medical College, Northwestern University Medical School, College of Physicians and Surgeons, Hahnemann Medical College, Bennett Medical College, Hering Medical College, Jenner Medical College, Illinois Medical College, American Medical Missionary College, College of Medicine and Surgery, National Medical University, Chicago College of Medicine and Surgery and Reliance Medical College.

Chicago

Rush Medical College.—This school was founded in 1837, organized in 1843, was the medical department of Lake Forest University from 1887 until 1898, when it became affiliated with the University of Chicago. The first class graduated in 1844. The faculty is composed of 89 professors, 141 associates, instructors, etc., a total of 230. The requirements for admission are a four-year high school education and, in addition thereto, two years of college work, including courses in college chemistry, physics and biology, and a reading knowledge of German or French. The course covers four years of nine months each. An optional fifth year, consisting of a hospital interneship or of a fellowship in one of the departments is offered. All freshmen and sophomore studies are given at the University of Chicago. The last two years are given in the clinical buildings at the corner of Wood and Harrison Streets. The total fees are $180 each year. A matriculation fee of $5 is paid but once, and there are incidenta [illegible] annually. The Dean is Dr. John M. [illegible] Total registration 1908-9 was 488; g [illegible] session begins Oct. 1, 1909, and ends June 18, 1910.

Northwestern University Medical School, Dearborn Street, between Twenty fourth and Twenty-fifth [illegible] 1859 as the Medical Department of Lind [illegible] became independent as the Chicago Medical [illegible] Northwestern University in 1869, but retain [illegible] Medical College until 1891, when the presen [illegible] faculty comprises 54 professors and 89 lecturers and assistants, a total of 143. The requirements for admission are such as will admit to the College of Liberal Arts of Northwestern University plus two years of college work including courses in physics, chemistry, biology and modern languages. The course covers four years of thirty-six weeks each. The fees for the first year are $194; second year, $200; third year, $191.50, and fourth year, $185. The Secretary is Dr. Charles Louis Mix. The total registration for 1908-9 was 621; graduates, 172. The fiftieth session begins Oct. 5, 1909, and ends May 29, 1910.

College of Physicians and Surgeons, Honore and Congress Streets.—Organized in 1882. The first class graduated in 1883. It became the Medical Department of the University of Illinois in 1896. The faculty is composed o [illegible] nts and instructors, a total of 198. The [illegible] the first two years, $150 for the third, ar [illegible] ar. The Dean is Dr. William E. Quine, 10 [illegible] istration for 1908-9 was 517; graduates, [illegible] session begins Sept. 28, 1909, and ends [illegible]

American Medical Missionary College, 888 Thirty-fifth Place.—Organized in 1895. The first class graduated in 1899. Part of the work is given at Battle Creek, Michigan. The faculty numbers 22 professors and 10 assistants, a total of 32. The course covers four years of nine months each. Total fees for the four years respectively are $83, $82, $75, $75. The Secretary is Dr. E. L. Eggleston, Battle Creek, Mich. Total registration for 1908-9 was 60; graduates, 5. The fifteenth session opens Sept. 14, 1909, and closes June 15, 1910.

Chicago College of Medicine and Surgery, 337 South Lincoln Street.—Organized in 1901 as the American College of Medicine and Surgery (Chicago Eclectic Medical College). The latter part of the name was dropped in 1902 when it became the Medical Department of Valparaiso University. Eclecticism was dropped in 1905. The name was changed to the above in 1907. The course covers four years of eight months each. The faculty consists of 37 professors and 34 lectur[illegible] total of 71. The total fees for each of the f[illegible] are $120, $115, $100 and $115. The total [illegible] was 396; graduates, 80. The ninth sessio[illegible] 9, and ends May 16, 1910. The Secretary is Dr. J. N. Roe.

Hahnemann Medical College and Hospital of Chicago, 2811 Cottage Grove Avenue.—Organized in 1859. The first class was graduated in 1861. The faculty includes 38 professors and 46 lecturers, assistants, etc., a total of 84. The tuition fees are $100 each year. The Registrar is Dr. W. Henry Wilson. The total registration for 1908-9 was 132; graduates, 25. The fiftieth session begins Sept. 27, 1909, and ends May 26, 1910.

Hering Medical College, Homeopathic, Wood and York Streets.—Organized in 1892. The first class graduated in 1893. The faculty consists of 26 professors and 24 assistants, instructors, etc., a total of 50. The tuition fees are $100 per year. The Dean is Dr. Robert N. Morris. The total registration for 1908-9 was 40; graduates, 10. The next session begins Sept. 28, 1909, and ends June 2, 1910.

Illinois Medical College, Corner Washington Boulevard and Halsted Street.—It was organized in 1894. Classes were graduated in 1895 and in all subsequent years. The faculty consists of 38 professors and 20 lecturers and assistants, a total of 58. The course covers four years of seven months each. The fees are about $125 each year. The President is Dr. J. F. Burkholder. The total registration for 1908-9 was 62; graduates, 16. The fifteenth session begins Sept. 2, 1909, and ends April 29, 1910.

Bennett Medical College, Fulton and Ada Streets.—Organized in 1868 as the Bennett College of Eclectic Medicine and Surgery. Dropped Eclecticism in 1909. The first class graduated in 1870. The faculty numbers 57. The course covers four years of thirty weeks each. Fees for each year are $100, with a matriculation fee, paid once, of $5. The President is Dr. John D. Robertson. The total registration for the college year 1908-9 was 186; graduates, 39. The next session begins Sept. 21, 1909, and ends May 23, 1910.

College of Medicine and Surgery, Physiomedical, 721-725 South Wood Street.—Organized in 1885 as the Chicago Physiomedical institute. The first class graduated in 1886. In 1891 the name was changed to the Chicago Physiomedical College. In 1899 it took its present name. The faculty numbers 49. The school year has three divisions of 16 weeks each. Attendance on any two will constitute a year's work. Fees for the four years respectively are $115, $110, $110 and $135. The Secretary is Dr. William F. Schaare. The total registration for 1908-9 was 33; graduates, 10. The next session begins Sept. 21, 1909, and ends May 11, 1910.

Jenner Medical College, a night school, located at 196 East Washington Street.—Organized in 1892. Classes were graduated in 1896 and in all subsequent years. The faculty numbers 50. Registrar, Dr. John D. MacKellar. Total registration for 1908-9 was 112; graduates, 12. The next session begins Aug. 30, 1909, and ends July 1, 1910.

National Medical University, a night school located at 531 Wells Street.—Organized in 1891 as the National Homeopathic Medical College. The first class was graduated in 1902. In 1895 the word "Homeopathic" was dropped. It took the above name in 1900. The faculty numbers 36. The total fees are $150 each year. The Dean is Dr. L. D. Rogers. Total registration for 1908-9 was 150; graduates, 12. *Reported to be not in good standing by the Illinois State Board of Health.*

Reliance Medical College. A night school, located at Washington Boulevard and Halsted Street.—Organized in 1907. The faculty numbers 65. The total fees are $130 for each of the first two years and $125 for each of the last two. Registration for 1908-9 was 83; graduates, 18. The President is Dr. J. F. Burkholder. The next session begins Sept. 7, 1909, and ends June 29, 1910.

INDIANA

Indiana, population 2,710,898, has two medical colleges, the Indiana University School of Medicine and the Physio-Medical College of Indiana. Both are located at Indianapolis, a city of 219,154 people, except that the work of the first two years of the Indiana University School of Medicine is offered also at Bloomington, population 5,000, the seat of the University.

Bloomington and Indianapolis

Indiana University School of Medicine.—Organized in 1893, but did not give all of the work of the first two years of the medical course until 1905. In 1907, by union with the State College of Physicians and Surgeons, the complete course in medicine was offered. In 1908 the Indiana Medical College, which was formed in 1907 by the merger of the Medical College of Indiana (organized in 1879) and the Fort Wayne College of Medicine (organized in 1879) merged into it. The faculty consists of 99 professors and 76 lecturers, associates and assistants, a total of 175. In 1909, besides a four-year high school education, one year, and in 1910 and thereafter, two years of collegiate work will be required for admission. The work of the first two years may be taken either at Bloomington or at Indianapolis. The clinical work is all done at Indianapolis. A fifth optional year leading to the "M.D. *cum laude*" has been added. The Secretary at Bloomington is Dr. B. D. Myers; at Indianapolis, Dr. Edmund D. Clark, Newton-Claypool Bldg. The total registration for 1908-9 was 266; graduates, 64. The next session begins Sept. 21, 1909, and ends June 22, 1910.

Physiomedical College of Indiana. Fourteenth Street and College Avenue.—Organized in 1873. The first class graduated in 1874. The Dean is Dr. C. T. Bedford. The total registration for 1908-9 was 19; graduates, 5.

IOWA

Iowa, population 2,205,690, has four medical colleges. The College of Medicine of the State University of Iowa and the College of Homeopathic Medicine of the State University of Iowa are located in Iowa City, population 8,497. In Des Moines, population 78,323, is the College of Medicine of Drake University. In Sioux City, population 42,520, is the Sioux City College of Medicine.

Des Moines

Drake University College of Medicine.—First two years given on the University Campus, University Avenue, between Twenty-fifth and Twenty-eighth Streets, the clinical years at Fourth and Center Streets. Organized in 1882 as the Iowa College of Physicians and Surgeons. The first class graduated in 1883. In 1887 it became affiliated with and in 1900 became the Medical Department of Drake University. The faculty consists of 21 professors and 26 assistants, lecturers, etc., a total of 47. Beginning with the session of 1910-11 two years of collegiate work, including courses in physics, chemistry and histology, will be required for admission. The work covers four years of nine months each. The total fees are $75 each year. The Dean is Dr. William Wilson Pearson The total registration for 1908-9 was 130; graduates, 19. The twenty-seventh session begins Sept. 20, 1909, and ends June 15, 1910.

Iowa City

State University of Iowa College of Medicine. University Campus.—Organized in 1869. First session began in 1870. First class graduated in 1871. The faculty is made up of 20 professors, 20 lecturers, demonstrators and assistants, a total of 32. For the session of 1909-10 one year and for the session of 1910-11 and thereafter two years of collegiate work, including courses in physics, chemistry and biology, will be required for admission. The course of study covers four years of thirty-six weeks each. Total fees for each year are $50 plus a matriculation fee of $10 paid but once and a graduation fee of $10. The Dean is Dr. James R. Guthrie, Dubuque; Vice-Dean, Dr. Walter L. Bierring, Iowa City. Total number of students registered for 1908-9 was 266; graduates, 41. The 40th session begins Sept. 20, 1909, and ends June 15, 1910.

State University of Iowa College of Homeopathic Medicine.—Organized in 1877. The first class graduated in 1878. The faculty is composed of 10 professors and 15 lecturers and assistants, a total of 25. The work of the first two years is taken in classes with the students of the College of Medicine of the State University of Iowa. The fees are $50 each year, plus a matriculation fee of $10, paid but once and a graduation fee of $10. The Dean is Dr. George Royal. Total registration for 1908-9 was 42; graduates, 7. The thirty-second session begins Sept. 20, 1909. and ends June 15, 1910.

Sioux City

Sioux City College of Medicine. corner of Fourteenth and Jones Streets.—Organized in 1891. The first class graduated in 1893. Teaches only the last two or clinical years of the medical course. The total registration for 1908-9 was 20; graduates, 6. The Dean is Dr. F. E. Franchere.

KANSAS

Population 1,612,471, has three medical colleges. Kansas Medical College is in Topeka, population 41,880, and the Western Eclectic College of Medicine and Surgery is at Kansas City. The School of Medicine of the University of Kansas gives its first two years in Lawrence, population 12,123, and the last two years in Rosedale, a suburb of the two Kansas Cities, which together have a population of 260,288.

Kansas City

Western Eclectic College of Medicine and Surgery, Central and Simpson Avenues.—Organized at Kansas City, Mo., in 1898 as the Eclectic Medical University. Moved to Kansas City, Kan., in 1907. Took the present name in 1908. First class graduated in 1900. The faculty numbers 32. Fees for the four years respectively are $90, $95, $100 and $115. Course covers four years of about eight months each. The Secretary is Dr. W. H. Smith. The total registration for 1908-9 was 50; graduates, 7. The twelfth session begins Sept. 6, 1909, and ends April 30, 1910.

Lawrence and Kansas City

University of Kansas School of Medicine.—Organized in 1880. In 1905 it merged with the Kansas City (Mo.) Medical College, founded in 1869, the College of Physicians and Surgeons, founded in 1894, and the Medico-Chirurgical College, founded in 1897. The faculty, including lecturers and clinical assistants, numbers 79. The requirements for admission are two years of collegiate work. The course covers four years of about nine months each. The total fees are, for the first two years, $60 per year (and for non-residents of the state $70); for the last two years, $100 per year. The Dean at Lawrence is Dr. Mervin T. Sudler. The Dean at Kansas City is Dr. George Howard Hoxie. The total registration for 1908-9 was 90; graduates, 7. The thirtieth session begins Sept. 15, 1909, and ends June 8, 1910.

Topeka

Kansas Medical College, 521 Quincy Street.—Organized in 1890. The first class graduated in 1892. It has been the Medical Department of Washburn College since 1893. It has a faculty of 31 professors and 16 lecturers and assistants, a total of 47. The course covers four years of thirty weeks each. Fees, $65 yearly. The Dean is Dr. William E. McVey. Total registration for 1908-9 was 68; graduates, 17. The twentieth session begins Sept. 14, 1909, and ends June 8, 1910.

KENTUCKY

Kentucky, population 2,320,298, has three medical colleges. They are all situated in Louisville, a city of 226,129 inhabitants, and are as follows: University of Louisville Medical Department, Southwestern Homeopathic Medical College and Louisville National Medical College.

Louisville

University of Louisville Medical Department, Eighth and Chestnut Streets.—Organized in 1837 as the Louisville Medical Institute. The first class graduated in 1838, and a class graduated in each subsequent year except 1863. In 1846 the present name was assumed. In 1907 it absorbed the Kentucky University Medical Department. In 1908 it absorbed the Louisville Medical College, the Hospital College of Medicine and the Kentucky School of Medicine. It has a faculty of 28 professors and 27 lecturers and assistants, a total of 55. The course covers four years of thirty weeks each. The fees are $100 each year; graduation fee, $25. The Dean is Dr. T. C. Evans. The total registration for 1908-9 was 706, graduates, 181. The next session begins Nov. 15, 1909, and ends June 30, 1909.

Southwestern [illegible] al College and Hospital, Floyd and Walnut [illegible] in 1892. The first class graduated in 1894. [illegible] f 13 professors and 10 lecturers and assistar [illegible] urriculum covers four years of seven months each. Total fees: First three years $75 each and $95 for the fourth. The Dean is Dr. George S. Coon. Total number of students for 1908-9 was 13; graduates, 3. The seventeenth session begins Oct. 6, 1909, and ends May 19, 1910.

Louisville National Medical College. Colored. 112 West Green Street.—Organized in 1888. The first class graduated in 1889. The faculty numbers 28. The course covers four years of seven months each. The fees are $60, $55, $55 and $75 for the four years, respectively. The Dean is Dr. E. S. Porter. Total registration for 1908-9 was 40; graduates, 4. The next session begins Oct. 1, 1909, and ends May 18, 1910.

LOUISIANA

Louisiana, having a population of 1,539,449, contains two medical colleges: Medical Department of the Tulane University of Louisiana and Flint Medical College of New Orleans University. They are both situated in New Orleans, a city of 314,146 people.

New Orleans

Medical Department of the Tulane University of Louisiana. University Campus and 1551 Canal Street.—Organized in 1834 as the Medical College of Louisiana. Classes were graduated in 1835 and in all subsequent years, except 1863-1865, inclusive. It was transferred to Medical Department of the University of Louisiana in 1847 and became the Medical Department of the Tulane University in 1884. The faculty numbers 73. The course covers four years of seven months each. Total fees are $150 per year. The Dean is Dr. Isadore Dyer. The total registration for 1908-9 was 439; graduates, 103. The seventy-sixth session begins Oct. 1, 1909, and ends May 18, 1910.

Flint Medical College of New Orleans University. Colored. 1566 Canal Street.—Organized in 1889 as the Medical College of New Orleans University. A class was graduated in 1892 and in each subsequent year, except 1896. Took the above name in 1901. The faculty consists of 6 professors, 9 lecturers and instructors, 15 in all. The course covers four years of thirty weeks each. Total fees, $53 each year for the first three years and $60 for the fourth. The Dean is Dr. J. W. Thomas. Total registration for 1908-9 was 24; graduates, 6. The twentieth session begins Sept. 22, 1909, and ends May 12, 1910.

MAINE

Maine, population 714,494, has one medical college, located in Brunswick and Portland, the latter having a population of 55,167.

Brunswick-Portland

Medical School of Maine. The medical department of Bowdoin College. The first two years are given at Bowdoin College, Brunswick, the last two at Portland, building located on Chadwick Street.—Organized in 1820. The first class graduated in 1820. The faculty numbers 35. The course covers four years of eight months each. The total fees are $120 for the first year and $110 for each of the other three years. The Dean is Dr. Alfred Mitchell, Brunswick. Total number of students in 1908-9 was 81; graduates, 18. The eighty-ninth session begins Oct. 21, 1909, and ends June 22, 1910.

MARYLAND

Maryland, with a population of 1,275,434, contains seven medical colleges, all located in Baltimore, a city with 553,669 inhabitants. They are as follows: Johns Hopkins University Medical Department, School of Medicine of the University of Maryland, College of Physicians and Surgeons, Baltimore Medical College, Woman's Medical College, Atlantic Medical College and Maryland Medical College.

Baltimore

Johns Hopkins University, Medical Department, Washington and Monument Streets.—Organized in 1893. The first class graduated in 1897. The faculty consists of 23 professors and 89 clinical professors, etc., a total of 112. The requirements for admission demand that the applicant either has (a) completed the chemical-biologic course which leads to the A.B. degree in the university or (b) graduated at an approved college or scientific school and has a knowledge of French and German, physics, chemistry and biology, such as may be obtained from a year's course. The course extends over four years of eight and one-half months each. The charge for tuition is $200 per annum. The Dean is Dr. William H. Howell, 232 West Lanvale Street. Total registration for 1908-9 was 297; graduates, 50. The seventeenth session begins Oct. 5, 1909, and ends June 14, 1910.

College of Physicians and Surgeons, Calvert and Saratoga [illegible] n 1872. The first class graduated in 1873. [illegible] h Washington University School of Medicine. [illegible] 57. The work covers four years of eight months each. Total fees are $155 for each of the first three years and $185 for the fourth year. The Dean is Dr. Charles F. Bevan. The total number of students registered in 1908-9 was 252; graduates, 46. The thirty-eighth session begins Oct. 1, 1909, and ends June 1, 1910.

University of Maryland School of Medicine, Lombard and Greene Streets.—Organized in 1807 as the College of Medicine of Maryland. The first class graduated in 1810. In 1812 it became the University of Maryland School of Medicine. The faculty numbers 62. The course covers four years of eight months each. The total fees are $155 each year; graduation fee, $30. The Dean is Dr. R. Dorsey Coale. The total number of students registered in 1908-9 was 329; graduates, 89. The 103d session begins Oct. 1, 1909, and ends June 1, 1910.

Baltimore Medical College, Madison Street and Linden Avenue.—Organized in 1881. The first class graduated in 1882. The faculty numbers 69. The course covers four years of eight months each. Total fees are $125 per year. The Dean is Dr. David Streett. The total number of students registered in 1908-9 was 307; graduates, 57. The twenty-eighth session begins Sept. 20, 1909, and ends May 25, 1910.

Woman's Medical College of Baltimore, McCulloch and Hoffman Streets.—Organized in 1882. Classes graduated in 1883 and in each subsequent year, except 1898. The faculty numbers 32. The course covers four years of eight months each. The fees for the first three years are $106 each, and $86 for the last year. The Dean is Dr. John R. Abercrombie, 827 North Eutaw Street. The total registration for 1908-9 was 20; graduates, 5. The twenty-eighth session begins Oct. 1, 1909, and ends May 31, 1910.

Maryland Medical College, 1114 West Baltimore Street.—Organized in 1898. The first class graduated in 1899. The faculty is composed of 13 professors and 28 lecturers and assistants, a total of 41. The course covers four years of eight months each. Matriculation fee, $5; total fees for the first three years, $86 each; fourth year, $110. The Dean is Dr. Harry Gross. The total registration for 1908-9 was 95; graduates 37. The next session begins Sept. 25, 1909, and ends June 1, 1910.

[illegible] College, Mount Street, north of Riggs Ave- [illegible] 891 as the Southern Homeopathic Medical [illegible] assumed the above name and became non- [illegible] is Dr. Eldridge C. Price. The total registration for 1908-9 was 43; graduates, 25.

MASSACHUSETTS

Massachusetts, population 3,043,346, has four medical colleges: Medical School for Harvard University, Boston University School of Medicine, College of Physicians and Surgeons and Tufts College Medical School. They are all situated in Boston, a city of 602,278.

Boston

Medical School of Harvard University, Longwood Avenue.—Organized in 1782. The first class graduated in 1788. It has a faculty of 33 professors and 133 associates, assistants, etc., a total of 166. Candidates for admission "must present a degree in arts, literature, philosophy or science from a recognized college or scientific school, with the exception of such persons as may be admitted by special vote of the faculty." Fees: Matriculation, $5; tuition, $200 each year. The Dean is Dr. Henry A. Christian. The total registration for 1908-9 was 285; graduates, 55. The 128th session begins Sept. 30, 1909, and ends June 30, 1910.

Boston University School of Medicine, 80 East Concord Street.—Organized in 1873. In 1874 the New England Female Medical College, founded in 1848, was merged into it. The first class graduated in 1874. The faculty includes 29 professors, 35 associates, etc., a total of 64. The course covers four years of eight months each. Total fees for the first, second and third years, $127 each, and for the last year, $155. The Dean is Dr. John P. Sutherland, 302 Beacon Street. Total registration for 1908-9 was 95; graduates, 18. The thirty-seventh session begins Oct. 7, 1909, and ends June 1, 1910.

Tufts College Medical School, 416 Huntington Avenue.—Organized in 1893 as the Medical Department of Tufts College. The first class graduated in 1894. It has a faculty of 33 professors and 70 assistants, lecturers, etc., a total of 103. The course covers four years of eight months each. The total fees are $155 each year. The Secretary is Dr. Frederic M. Briggs, 31 Massachusetts Avenue. Total number of students for 1908-9 was 384; graduates, 61. The sixteenth session begins Sept. 29, 1909, and ends May 26, 1910.

College of Physicians and Surgeons, 517 Shawmut Avenue.—Organized in 1880. The first class graduated in 1882. The Dean is Dr. C. H. Cobb. The total registration for 1908-9 was 172; graduates, 12. The next session begins Sept. 16, 1909, and ends June 15, 1910.

MICHIGAN

Michigan, population 2,584,533, has four medical colleges. Two of these, the University of Michigan Department of Medicine and Surgery and the Homeopathic College of the University of Michigan, are located at Ann Arbor, a city of 14,645 people. Detroit, a city of 353,535 inhabitants, contains two medical colleges, the Detroit College of Medicine and the Detroit Homeopathic College.

Ann Arbor

University of Michigan Department of Medicine and Surgery.—Organized in 1850. The first class graduated in 1851. It has a faculty composed of 22 professors, 41 associates, instructors, etc., a total of 63. The entrance requirements are two years of college work, including courses in chemistry, physics and biology, with laboratory work, and a reading knowledge of one modern language. The curriculum embraces four years of nine months each. The total fees for Michigan students for the entire course of four years is $350 and for others about $400. The Dean is Dr. Victor C. Vaughan. The total registration for 1908-9 was 404; graduates, 74. The 60th session begins Oct. 5, 1909, and ends June 30, 1910.

University of Michigan Homeopathic College.—Organized in 1875. The first class graduated in 1877. The Dean is Dr. W. B. Hinsdale. The total registration for 1907-8 was 82; graduates, 15.

Detroit

Detroit College of Medicine, St. Antoine, Catherine and Mullett Streets and Gratiot Avenue.—Organized in 1885 by consolidation of Detroit Medical College, organized in 1868, and the Michigan College of Medicine, organized in 1880. The first class graduated in 1886. The faculty embraces 25 professors, 79 lecturers, instructors, etc., a total of 104. The course covers four years of eight months each. The Registrar is Dr. F. B. Walker. The total registration for 1908-9 was 161; graduates, 38. The twenty-fifth session begins Sept. 22, 1909, and ends May 26, 1910.

Detroit Homeopathic College, Lafayette Avenue and Third Street.—Organized in 1899. A class was graduated in 1900 and in each subsequent year. It has a faculty of 36. The course embraces four years of eight months each. Fees: From $75 to $95 per year. The Dean is Dr. D. A. MacLachlan; Registrar, J. M. Griffin. Total registration for 1908-9 was 34; graduates, 7. The eleventh session begins Sept. 14, 1909, and ends May 19, 1910.

MINNESOTA

Minnesota, population 2,025,615, contains one medical college, the College of Medicine and Surgery of the University of Minnesota, situated in Minneapolis. Minneapolis and St. Paul are practically one city, and have a combined population of 477,640.

Minneapolis

Univers[illegible]
—Organize[illegible]
Paul Medic[illegible]
first class [illegible]
Physicians [illegible]
the Home[illegible] and Surgery was merged and provision made for elective chairs in didactic materia medica and therapeutics. Students electing these courses on graduation will receive the degree of Doctor of Medicine in Homeopathy. The faculty includes 49 professors and clinical professors and 71 associate professors, assistants, etc., a total of 120. The curriculum covers four years of nine months each. The entrance requirements are two years of university work which must include one year each of physics, general chemistry, qualitative analysis, zoology or botany, and German or French, all in addition to a four-year high school course including Latin. The total registration for 1908-9 was 245, including 73 Hamline University students; the graduates of 1909 numbered 63, including 16 which were granted degrees by Hamline University. The twenty-second session begins Sept. 14, 1909, and ends June 9, 1910.

MISSISSIPPI

Mississippi, population 1,708,272, has two medical colleges; the Medical Department of the University of Mississippi is located at Oxford, a city of 2,000 inhabitants, and at Vicksburg, population 15,710. The Mississippi Medical College is located at Meridian, population 20,503.

Meridian

Mississippi Medical College, Fifth Street and Twenty-fourth Avenue.—Organized in 1906. The first class graduated in 1907. The faculty numbers 16. The Dean is Dr. T. A. Barber. The total registration for 1908-9 was 102; graduates, 15. The fourth session begins Oct. 1, 1909, and ends April 30, 1910.

Oxford and Vicksburg

University of Mississippi Medical Department.—Organized in 1903 Gave only the first two years of the medical course until 1909, when a clinical department was organized at Vicksburg. The course covers four years of eight and a half months each. The work of the first two years is given at Oxford and the last two at Vicksburg. The faculty numbers 30. The Dean at Oxford is Dr. W. S. Leathers; at Vicksburg, Dr. William Krauss. The total registration for 1908-9 was 27. The seventh session begins Sept. 23, 1909, and ends June 1, 1910.

MISSOURI

Missouri, population 3,363,153, has ten medical colleges. St. Louis, population 649,320, contains six of these, viz., St. Louis College of Physicians and Surgeons, American Medical College, the School of Medicine of St. Louis University, Washington University Medical Department, Barnes Medical College and the Hippocratean College of Medicine. Kansas City, which with Kansas City, Kan., has a total population of 260,288, has two colleges, namely: University Medical College and the Hahnemann Medical College of Kansas City. Ensworth Medical College is located in St. Joseph, population 118,004. The Department of Medicine of the University of Missouri is at Columbia, a town of 8,000 people.

Columbia

University of Missouri School of Medicine.—Organized at St. Louis in 1845; was discontinued in 1859, but was reorganized at Columbia in 1872. Teaching of the clinical years was suspended in 1909. The faculty includes 13 professors, 14 assistant professors, lecturers, etc., a total of 27. The course covers two years of nine months each. The candidate for entrance must present, beside the diploma from a recognized four-year high school, credentials of college work as follows: English, 6 hours; German, 6 hours; general zoology, 6 hours; general physics, 6 hours; inorganic chemistry, 6 hours. Beginning in September, 1910, the entrance requirements will be two years of college work, including the subjects specified. Total fees amount to about $70 each year. The Dean is Dr. C. M. Jackson. Total registration of students for 1908-9 was 47; graduates, 5. The next session begins Sept. 23, 1909, and ends June 9, 1910.

Kansas City

University Medical College of Kansas City, 911 East Tenth Street.—Organized in 1881 as the University of Kansas City Medical Department. The first class graduated in 1882. It was reorganized in 1888 under the present title. Its faculty comprises 47 professors and 19 lecturers and assistants, a total of 66. The course of study covers four years of thirty weeks each. The total fees for each year are $100; graduation fee, $25. The Dean is Dr. J. M. Frankenburger. The total registration for 1908-9 was 164; graduates, 47. The twenty-eighth session begins Sept. 8, 1909, and ends May 13, 1910.

Kansas City Hahnemann Medical College, 1020 East Tenth Street.—Organized in 1888 as the Kansas City Homeopathic Medical College. The first class graduated in 1899. In 1902 it united with the Hahnemann Medical College of the Kansas City University, taking the present title. The Dean is Dr. William E. Cramer. Total registration for 1908-9 was 46; graduates, 14.

St. Joseph

The Ensworth Medical College, Seventh and Jule Streets.—Organized in 1876 as the St. Joseph Hospital Medical College. In 1882 it merged with the College of Physicians and Surgeons to form the St. Joseph Medical College. In 1888 changed name to Ensworth Medical College. In 1905 merged with the Central Medical College, organized in 1894, to form the Ensworth-Central Medical College. In 1907 the present title was resumed. The faculty numbers 34. The course covers four years of eight months each. The fees for the four years respectively are $90, $95, $75 and $95. The Secretary is Dr. T. E. Potter. Total registration for 1908-9 was 72; graduates, 24. The next session begins Sept. 20, 1909, and ends May 10, 1910.

St. Louis

Washington University Medical Department, 1806 Locust Street.—Organized in 1842 as the Medical Department of St. Louis University. In 1855 it was chartered as an independent institution under the name of St. Louis Medical College. The first class graduated in 1843. In 1891 it became the Medical Department of Washington University. In 1899 it absorbed the Missouri Medical College. The faculty comprises 48 professors, 51 lecturers and instructors, a total of 99. The course is four years of eight months each. The total fees for the four years are respectively $137.50, $132.25, $117.25 and $101.25. The Dean is William H. Warren, Ph.D. The total registration for 1908-9 was 201; graduates, 48. The next session begins Sept. 21, 1909, and ends June 2, 1910.

St. Louis University School of Medicine, Grand Avenue and Caroline Street.—Organized in 1901 by union of Marion-Sims Medical College, organized in 1890, and Beaumont Hospital Medical College, organized in 1886. It became the Medical Department of St. Louis University in 1903. The faculty is composed of 39 professors, 82 lecturers and assistants, a total of 121. The curriculum covers four years of eight months each. The total fees are $110 each year. The Dean is Dr. E. P. Lyon. The total registration for 1908-9 was 243; graduates, 47. The next session begins Oct. 1, 1909, and ends May 29, 1910.

St. Louis College of Physicians and Surgeons, Jefferson Avenue and Gamble Street.—Organized in 1869. Classes graduated in 1870 and in each subsequent year until 1873, when it suspended. It was reorganized in 1879. Classes graduated in 1880 and subsequent years. It has a faculty of 25 professors, 24 lecturers, instructors, etc., a total of 49. The course covers four years of seven months each. Total fees for each of the four years respectively are $105, $100, $100 and $105. The Dean is Dr. Waldo Briggs, 2600 Gamble Street. Total registration for 1908-9 was 224; graduates, 66. The next session begins Sept. 15, 1909, and ends May 6, 1910.

Barnes Medical College, Garrison and Lawton Avenues.—Organized in 1892. Classes graduated in 1893 and in all subsequent years, except 1899. The Secretary is Dr. C. M. Ament, 1025 Missouri Trust Building. Total registration for 1908-9 was 124; graduating class, 36.

American Medical College, Eclectic, 407 South Jefferson Avenue.—Organized in 1873. Two classes graduated each year from

1874 to 1883, inclusive. Since then one class has graduated each year. The Dean is Dr. J. J. Link. The total registration for 1908-9 was 28; graduates, 7. The next session begins Sept. 1, 1909, and ends May 4, 1910.

[illegible] OF MEDICINE, 3412 Morgan Street. A [illegible] in 1907. Its faculty numbers 28. During [illegible] s. The Dean is Dr. Emory Lanphear. The next session begins Sept. 6, 1909, and ends June 15, 1910.

NEBRASKA

Nebraska, population 1,068,484, has three medical colleges: The University of Nebraska College of Medicine and the John A. Creighton Medical College at Omaha, population 124,167, and the Lincoln Medical College at Lincoln, population 48,232.

Lincoln and Omaha

COLLEGE OF MEDIC[illegible] Eleventh and R Streets, Lincoln, and [illegible] Omaha.—Organized in 1881 as the C[illegible] first class graduated in 1882. It be[illegible] of Omaha University in 1891. In [illegible] University of Nebraska, with the present title. Two years of collegiate work are *required for admission. The first two years are given at Lincoln*; the last two at Omaha. The faculty is composed of 38 professors and 46 lecturers and instructors, total 84. The fees are approximately $100 *per annum. The total registration for* 1908-9 was 122; graduates, 9. The next session begins Sept. 21, 1909, and ends May 19, 1910.

Lincoln

LINCOLN MEDICAL COLLEGE. Eclectic. Corner 13th and P Streets. It is the Medical Department of Cotner University.—Organized in 1890. The first class graduated in 1891. The faculty numbers 44. The course of study covers four years of thirty-two weeks each. The total fees for the first year are $80; second and third, $75 each, and $85 for the fourth year, or $250 for all four years together. The Secretary is Dr. R. H. *Spradling*, 1315 O Street. The total registration for 1908-9 was 42; graduates, 9. The twentieth session begins Sept. 9, 1909, and ends June 9, 1910.

Omaha

JOHN A. CREIGHTON MEDICAL COLLEGE, Fourteenth and Davenport Streets. It is the Medical Department of Creighton University.—Organized in 1892. The first class graduated in 1895. It has a faculty of 35 professors and 16 associates, lecturers and assistants, a total of 51. The total registration for 1908-9 was 43; graduates, 1. The fifth session begins Sept. 30, 1909, and ends May 23, *1910*.

LONG ISLAND COLLEGE HOSPITAL, Henry Street, near Atlantic Avenue, Brooklyn.—Organized in 1858. The first class graduated in 1860. It has a faculty of 9 professors and 98 assistants, instructors, etc., a total of 107. The course covers four years of thirty weeks each. Fees: First year, $200; second, $200; third, $160, and $195 for the fourth year. The Secretary is Dr. Joseph H. Raymond. Total registration, 1908-9, was 364; graduates, 75. The fifty-second session begins Sept. 29, 1909, and ends June 1, 1910.

NEW YORK HOMEOPATHIC MEDICAL COLLEGE AND HOSPITAL, Eastern Boulevard, between Sixty-third and Sixty-fourth Streets.—Organized in 1858. Incorporated in 1860 as the Homeopathic Medical College for the State of New York. The present title was assumed in 1869. The first class graduated in 1861. The Dean is Dr. Royal S. Copeland. Total registration for 1908-9 was 109; graduates, 16.

NEW YORK MEDICAL COLLEGE AND HOSPITAL FOR WOMEN, 17-19 West *One* Hundred and *First* Street.—Organized in 1863. The *first class graduated in 1864. The Dean is Dr. Helen Cooley Palmer*. The total registration for 1908-9 was 24; graduates, 4.

UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE, First Avenue and Twenty-sixth Street.—Organized in 1898 by the union of the New York University Medical College, organized in 1841, and the Bellevue Hospital Medical College, organized in 1861. It is the Medical Department of New York University. The faculty is composed of 33 professors and 90 instructors, etc., in all 123. The course covers four years of eight months each. The fees are $200 per year. The Dean is Dr. Egbert Le Fevre. Total registration for 1908-9 was 445; graduates, 74. The twelfth session begins Sept. 29, 1909, and ends June 1, 1910.

Syracuse

SYRA[illegible] OF MEDICINE, 307-311 Orange Street.-[illegible] College of Physicians and Surgeons [illegible] he present title was assumed in 1875. [illegible] 'ollege was merged with it. The first cl[illegible] The faculty is composed of 15 profess[illegible] essors, lecturers and instructors, in all 57. The course covers four years of eight months each. The completion of one year in an accredited college of liberal arts is required for admission. Beginning September 1910 two years of such college work will be required for admission. The average total fees for each year are $172.25. The Dean is Dr. John L. Heffron. The total registration for 1908-9 was 149; graduates, 33. The thirty-eighth session begins Oct. 5, 1909, and ends June 8, 1910.

NORTH CAROLINA

North Carolina, population, 2,059,326, has four medical schools, one of which gives only the first two years of the *medical course. The Medical Department of the University of* North Carolina is located at Chapel Hill, population 1,100, and at Raleigh, population 14,225. The Leonard School of Medicine is at Raleigh. The North Carolina Medical College is at Charlotte, population 22,009. Wake Forest School of Medicine is at Wake Forest, population 823.

Chapel Hill and Raleigh

University of North Carolina Medical Department.—Organized in 1890. Until 1902 this school gave only the work of the first two years, when the course was extended to four years by the establishment of a department at Raleigh. The first class graduated in 1903. The faculty is composed of 22 professors and 23 lecturers, assistants, etc., a total of 45. The total fees for the four years respectively are $114, $116, $75 and $80. The Dean of the Department at Chapel Hill is Dr. G. H. Manning; at Raleigh, Dr. H. A. Royster. The total registration for 1908-9 was 113; graduates, 12. The twentieth session begins Sept. 6, 1909, and ends June 1, 1910.

Charlotte

North Carolina Medical College, Church and Sixth Streets.—Organized in 1887 at Davidson as the Davidson School of Medicine. It was a preparatory school only, not granting any degrees until 1893, when it was chartered under its present name. The first class was graduated in 1893. Removed to Charlotte in 1907. The faculty numbers 29. The course covers four years of eight months each. Fees: First three years, $85 each, and $100 for the fourth year. The Dean is Dr. Walter O. Nisbet. The total registration for 1908-9 was 94; graduates, 17. The next session begins Sept. 8, 1909, and ends April 30, 1910.

Raleigh

Leonard Medical School.—Colored. This department of Shaw University was established in 1882. Classes were graduated in 1886, 1888 and in all subsequent years. It has a faculty of 10. The course covers four years of seven months each. The total fees for each year a [illegible], $10. The Dean is Dr. James McKee. Total [illegible] was 125; graduates, 22. The 28th session be[illegible]d ends May 12, 1910.

Wake Forest

Wake Forest College School of Medicine.—This school was organized in 1902. The faculty numbers 10. It only gives the first two years of the medical course, which constitute a part of the course for the B.S. degree. Each annual course extends over nine months. The fees are $100 each year. The Dean is Dr. John Brewer Powers. The total registration for 1908-9 was 53. The eighth session begins Sept. 6, 1909, and ends May 25, 1910.

NORTH DAKOTA

North Dakota, population 383,226, has one medical college, the College of Medicine of the State University of North Dakota, which is situated at University near Grand Forks.

University

University of North Dakota College of Medicine.—Organized in 1905. The faculty is composed of 9 professors and 7 instructors, a total of 16. The course consists of two years' academic work and two years of medical college subjects, occupying nine months each year. The total fees for each of the medical years are $50. The Dean is M. A. Brannon, A.M. The total registration for 1908-9 was 22. The fifth session begins Sept. 21, 1909, and ends June 16, 1910.

OHIO

Ohio, population 4,448,677, has eight medical colleges. Three of these, the Ohio-Miami Medical College of the University of Cincinnati, the Eclectic Medical Institute, and Pulte Medical College, are located in Cincinnati, a city of 345,230 inhabitants. Cleveland, population 460,327, contains three medical schools: Western Reserve University Medical College, Cleveland College of Physicians and Surgeons and the Cleveland Homeopathic Medical College. Columbus, population 145,414, contains one medical college, the Starling-Ohio Medical College. Toledo, with 159,980 people, has one medical school, the *Toledo Medical College.*

Cincinnati

The Ohio-Miami Medical College of the University of Cincinnati.—Organized in 1909 by the union of the Ohio Medical College (founded in 1819) with the Miami Medical College (founded in 1852). The Ohio Medical College became the Medical Department of the University of Cincinnati, April 26, 1896. Under a similar agreement, March 2, 1909, Miami Medical College also merged into the University when the present title was taken. The agreement gave the university entire control and both colleges turned over all their property to the City of Cincinnati for the University and gave up their own corporate existence. The faculty now consists of 50 professors, 13 associate and assistant professors, and 65 lecturers, instructors, etc., a total of 128. The course covers four years of eight months each. The fees are a tuition fee of $125 a year; a matriculation fee of $5, payable but once, and a graduation fee of $25. The Secretary is Dr. E. Otis Smith. The next session begins Sept. 27, 1909, and ends June 4, 1910.

Eclectic Medical Institute, 1009 Plum Street.—Organized in 1832 at Worthington as the Worthington Medical College. Removed to Cincinnati in 1843. In 1845 it was chartered under its present title. In 1857 the American Medical College, organized in 1839, was merged into it, and in 1859 the Eclectic College of Medicine and Surgery, organized in 1856, merged into it. Classes were graduated in 1833 and in all subsequent years except 1839 to 1843 inclusive. It has a faculty of 19 professors and 6 lecturers and assistants, a total of 25. The course covers four years of thirty weeks each. The fees are $90 for each year. The Dean is Dr. Rolla L. Thomas, 792 East McMillan Street. Total registration for 1908-9 was 81; graduates, 16. The next session begins Sept. 20, 1909, and ends May 4, 1910.

Pulte Medical College. Homeopathic. Mound and Seventh Streets.—Organized in 1872. The first class graduated in 1873. The faculty numbers 37. The fees for each of the four years are respectively $85, $82, $75 and $100. The Dean is Dr. Charles E. Walton. Total enrolment for 1908-9 was 16; graduates, 3. The 38th session begins Sept. 30, 1909, and ends May 25, 1910.

Cleveland

The Cleveland College of Physicians and Surgeons, Central Avenue and East Fourteenth Street.—Organized in 1863 as Charity Hospital Medical College, became the Medical Department of Wooster University in 1869 and the Medical Department of the Ohio Wesleyan University in 1896, when it assumed its present title. Classes were graduated in 1865 and in all subsequent years except 1881. The faculty is composed of 33 professors, 28 lecturers, assistants, etc., 61 in all. The total fees for the four years respectively are $130, $130, $117 and $110. The curriculum covers four years of eight months each. The Dean is Dr. R. E. Skeel, 314 The Osborn. Nova Scotia

Halifax Medical College, Medical Faculty of Dalhousie University, Halifax.—Organized 1867 as Halifax School of Medicine, united same year with Dalhousie University, separately incorporated 1876, affiliated with Dalhousie University 1885, first class graduated 1872 and a class graduated each subsequent year except 1873 and 1886. The course covers four years. The Dean is Dr. George L. Sinclair. The Secretary is Dr. A. W. H. Lindsay. The total registration for 1908-9 was 61; graduates, 8. The next session begins Aug. 26, 1909, and ends Aprll 28, 1910.

Ontario

University of Toronto, Faculty of Medicine, Toronto.—Organized 1843 as the Medical Faculty of King's College. Abolished in 1853. Re-established in 1887. The course of study covers five years of eight months each. In 1902 it absorbed Victoria University and in 1903 it absorbed Trinity Medical College. The Dean is Dr. A. R. Reeve; Secretary, Dr. A. Primrose. The total registration for 1908-9 was 630; graduates, 90. The next session begins Oct. 1, 1909, and ends May 13, 1910.

Medical Faculty of Queen's University, Kingston.—Organized 1854, first class graduated in 1855, and a class graduated each subsequent year. The faculty was originally a department of the University, but a separation took place in 1866, when the school was conducted under the charter of the Royal College of Physicians and Surgeons at Kingston. In 1897 the school again became an integral part of Queen's University. The fees amount to $100 each year; fee for the M.D., C.M. degrees, $30. A five year medical course is required. The total registration in 1908-9 was 208; graduates, 40. The Dean is Dr. A. R. B. Williamson. The next session begins Sept. 29, 1909, and ends April 27, 1910.

Medical Department of Western University, London.—Organized in 1881, first class graduated in 1883 and a class graduated each year subsequently. The Registrar is Dr. W. E. Waugh. Total registration for 1908-9 was 104; graduates, 27. The next session begins Sept. 21, 1909, and ends May 1, 1910.

Quebec

Medical Faculty of McGill University.—Founded 1824 as Montreal Medical Institution; became the Medical Faculty of McGill University in 1829; first class graduated under the university auspices in 1833. No sessions between 1836-39 owing to political troubles. In 1905 absorbed Faculty of Medicine University of Bishop College. The course now extends over five years. The faculty numbers 95. Total registration for 1908-9 was 328; graduates, 71. The Registrar is Dr. John W. Scane. The next session begins Oct. 1, 1909, and ends June 8, 1910.

Laval University, Medic [illegible] bec and Montreal.—The Quebec school of [illegible] n 1848, became in 1852 Medical Department [illegible] first class graduated in 1855, and a class graduated each subsequent year. Department organized in Montreal in 1878. The course extends over five years. The Deans are Dr. Laurent Catellier, Quebec, and Dr. E. P. Lachapelle, Montreal.. Total registration at the two departments, 1908-9, was 309; graduates, 55. The next session begins Sept. 15, 1909, and ends June 20, 1910.

FOREIGN MEDICAL COLLEGES

ARGENTINE REPUBLIC

Buenos Ayres.—Universidad Nacional de Buenos Aires.
Cordova.—Universidad Nacional.

AUSTRALIA

Adelaide.—Universidad Nacional.
Melbourne.—University of Melbourne.
Sydney.—University of Sydney.

Sassari.—Regia Università degli Studi.
Siena.—Regia Università degli Studi.
Turin.—Regia Università degli Studi.

JAPAN

Kyoto.—Imperial University (part of medical school is located at Fukuoka).
Tokyo.—Imperial University (Tokio Medical College became Medical Department in 1877).

Medical schools are located also at Chiba, Sendai, Okayama, Kanazawa and Nagasaki.

MEXICO

Mexico.—Escuela de Medicina.

NETHERLANDS

Amsterdam.—Universiteit van Amsterdam.
Groningen.—Rijks-Universiteit te Groningen.
Leyden.—Rijks-Universiteit.
Utrecht.—Rijks-Universiteit.

NEW ZEALAND

Wellington.—University of New Zealand (affiliated with the University of Cambridge, England).

NORWAY

Christiania.—Kongelige Frederiks Universitet.

PERU

Lima.—Universidad Mayor de San Marcos.

PORTUGAL

Coimbra.—Universidade de Coimbra.
Lisbon.—Escola Medico-Cirurgica.

ROUMANIA

Bukharest.—Universitatea din Bucuresti.
Jassy.—Universitatea din Jasi.

RUSSIA

Helsingfors, Finland.—Kejserliga Alexanders Universitet.
Jurjev (formerly Dorpat).—Imperatorskij Jurjevskij Universitet.
Kazan.—Imperatorskij Kasanskij Universitet.
Kharkof.—Imperatorskij Charkovskij Universitet.
Kief.—Imperatorskij Universitet Sv. Vladimira.
Moscow.—Imperatorskij Moskovskij Universitet.
Odessa.—Imperatorskij Novorossijskij Universitet.
St. Petersburg.—Imperatorskij St. Petersbergskij Universitet: Including Vojenno-Medicinskaja Akademija (Military Medical Academy) and Zenskij Medicinskij Institut (Medical High School for Women).
Tomsk, Siberia.—Tomskij Universitet.
Warsaw.—Imperatorskij Varsavskij Universitet.

SCOTLAND

Aberdeen.—University of Aberdeen.
Dundee.—University of St. Andrews (University College).
Edinburgh.—University of Edinburgh.
Edinburgh.—School of Medicine of the Royal Colleges (including the Surgeons' Hall School).
Glasgow.—University of Glasgow (including Queen Margaret College).
Glasgow.—Anderson's College Medical School.
Glasgow.—St. Mungo's College and Glasgow Royal Infirmary.
Glasgow.—Western Medical School.

SPAIN

Barcelona.—Universidad de Barcelona.
Cadiz.—Facultad de Medicina.
Granada.—Universidad de Granada.
Madrid.—Universidad de Central de Espana.
Santiago.—Universidad.
Saragossa.—Universidad.
Seville.—Universidad de Sevilla. (To this university also belongs the Medical Faculty at Cadiz.)
Valencia.—Universidad Literaria.
Valladolid.—Universidad.

SWEDEN

Lund.—Kungl, Karolinska Universitetet.
Stockholm.—Karolinska Institutet (Medico-Chirurgical Institute). (This institute has the same chancellor as the universities at Lund and Upsala, and is guided by a similar constitution.)
Upsala.—Kungl, Universitetet i Upsala.

SWITZERLAND

Basel.—Universität.
Berne.—Kantonale Universität.
Geneva.—Université de Genève.
Lausanna.—Université.
Zurich.—Universität.

SYRIA

Beirut.—Syrian Protestant College.
Beirut.—Université Saint Joseph de Beyrouth.

URUGUAY

Montevideo.—Universidad.

WALES

Cardiff.—University of Wales (Cardiff School of Medicine).

MEDICAL STANDARDS ABROAD

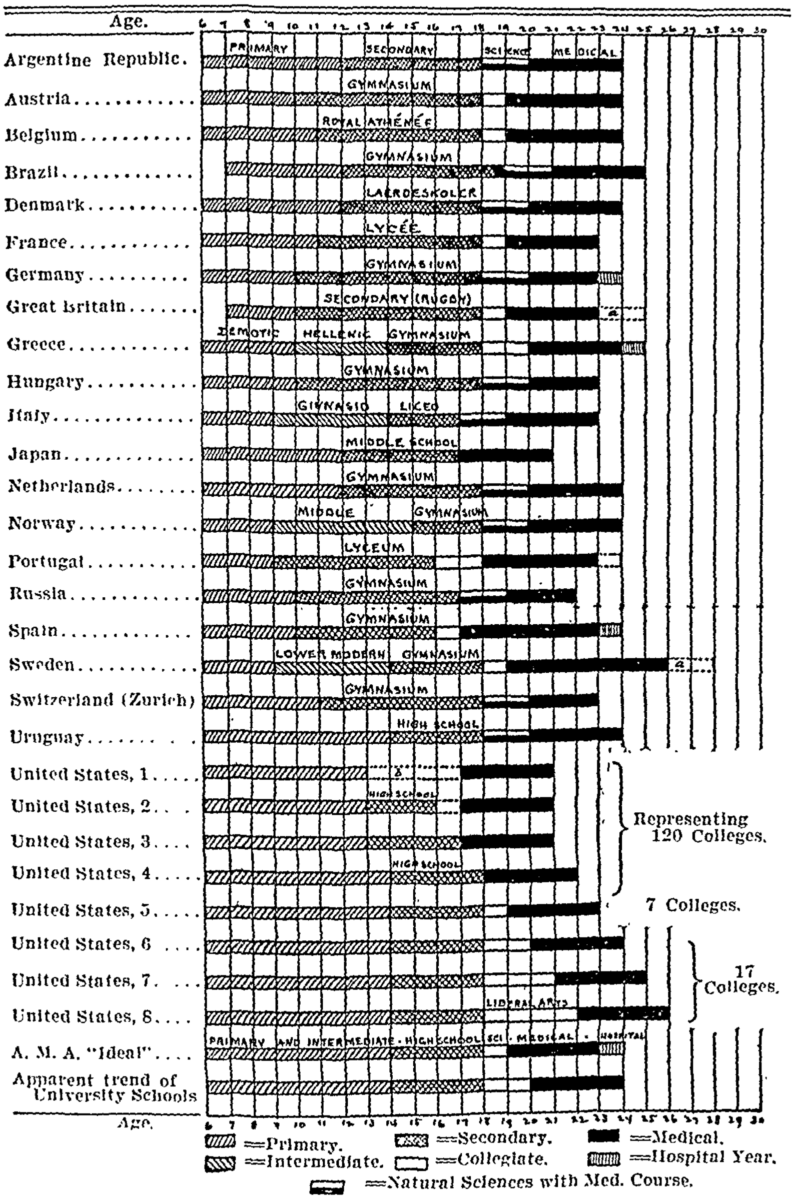
A list of medical colleges of all foreign countries shows a total of 165 such colleges outside the United States, while this country alone has 144. In other words, of the 309 medical colleges in all countries, the United States has 144, or 47 per cent., while the 30 other nations altogether have only 165, or 53 per cent. All European medical schools are medical faculties of universities or are under the direct control of universities, and there are no proprietary schools such as predominate in this country.

The information regarding preliminary education as well as collegiate and medical was obtained from original sources and from foreign publications. The data agree with the reports of the United States Bureau of Education, and in most instances have been confirmed by reports from the American consuls abroad.

The requirements in sixteen countries of Europe, Japan and three countries of South America are graphically presented in a chart, in which each division of education is shown according to the ages at which students are in attendance. The shaded portions of the bands represent primary and secondary education, the black portions the medical, and the white portions represent the requirements of higher preliminary education, including work in physics, chemistry and biology. The chart allows valuable comparisons to be made and, as measured by years, shows more of a uniformity of educational standards than one would expect. It is interesting to note how sharply the line representing the age of 18 separates the secondary from higher education.

The age at the completion of the medical course in each country, as shown in the chart, with one or two exceptions, represents the lowest age at which the student can secure the right to practice medicine, disregarding the rare exceptions when the student graduates at an earlier age. The average age is one or two years higher than is shown in the chart, since the regular course of study between the ages of 6 and 24 is often broken by sickness, failure to receive promotion, or other causes.

PRELIMINARY AND MEDICAL EDUCATION AT HOME AND ABROAD



In the majority of foreign countries secondary education begins from two to five years earlier than in this country and with a few exceptions has no direct connection with the elementary. In fact, in several European countries, in Great Britain and in France, for example, it appears that the majority of students entering the secondary schools secure their elementary instruction from private tutors or in preparatory courses offered by the secondary schools, rather than in the regular elementary schools.

It should be stated that, although the expression of educational requirements in terms of years, or months, or by the ages of students does not actually measure the value of the education obtained, nevertheless a knowledge of the minimum time requirements in other countries is of importance, and a comparison with the minimum time requirements in our own country is of much value. This chart is of peculiar interest. Educators of high repute have stated that the courses of study in the secondary schools of several European countries are the equivalent of a four-year high school course in this country, plus about two years of work in a college of liberal arts. It is, therefore, of some importance for us to know that the secondary schools of Europe may be completed at the age of 18, whereas two years of work in a college of arts in this country can rarely be completed before the age of 20. In other words, taking the above claims for granted, it is important for us to know that the training of 12 years, between the ages of 6 and 18, in Germany and other European countries, is the equivalent of 14 years' training in this country between the ages of 6 and 20.

Of all the countries named in the chart the United States is the only one which does not require preliminary work in physics, chemistry and biology of every medical student. In some of the countries named the work is taken in the first one or two years of the medical course, along with the usual medical studies, while in others, notably in France, Belgium and Sweden, it must be taken in a college of science or philosophy. In still others, as in Austria and in Great Britain, the work may be taken either in a college of liberal arts or in the medical school.

In France this work was given as a part of the regular medical course until in 1893, when it was transferred to the college of science, because the laboratories and trained instructors in those colleges made it certain that the courses would be thoroughly taught.

Only one year devoted to the preliminary scientific studies is required by all but two of the countries named or else the work extends through about two years along with regular medical subjects. In no instance is more than two years of college work devoted entirely to preliminary study.

In six of the countries named, disregarding rare exceptions, the earliest age at which the right to practice medicine can be secured, is 23. In three countries the age limit is 25 or beyond. But in the great majority the age limit is 24, and the entire course of elementary, secondary, college and medical education is completed in 18 years. This agrees with the "ideal standard" adopted at Portland, Ore., in 1905 by the American Medical Association, as well as with the combined course by which the students can secure the degrees of B.S. and M.D. in six years and which has been adopted by a number of colleges.

The well-known diversity of standards of medical education in the United States at the present time is also shown in the chart. Preliminary standards range from a common school education up to the requirement of a college degree. Of the 144 colleges in the United States, 121 require a four-year high school education or less, as shown in Groups 1 to 4, while 24 colleges are now requiring one or more years of work in a college of arts, 14 of these having raised their requirements in the past 3 years. There are now in the United States several medical schools which are probably equal to any found abroad.

The educational standards in the countries regarding which definite information has been obtained are briefly stated as follows:

Argentine Republic.—Elementary education extends between the ages of 6 and 14, and secondary education between the ages of 12 and 18, thereby overlapping the elementary by two years. Twelve years of study, therefore, lead to the medical course, which covers six years, including preliminary work in physics, chemistry and biology. The complete course requires 18 years, and the minimum age at the completion of the course is 24.

Austria.—Elementary education extends between the ages of 6 and 14, overlapping the gymnasium course by four years, the latter extending between the ages of 10 and 18. Twelve years of study, therefore, admit to medicine. The medical course covers six years and includes preliminary courses in physics, chemistry and biology. The total time required is 18 years and the minimum age at completion is 24.

Belgium.—Elementary education extends between the ages of 6 and 14, overlapping the work in the Royal Athénées, the secondary schools, by three years, the latter extending between the ages of 11 and 18. The time spent in the primary and secondary schools is, therefore, 12 years. An additional year devoted to physics, chemistry and biology in a college of science admits to the five-year medical course. The time necessary to complete the work is 18 years and the minimum age at completion is 24.

Brazil.—Elementary education extends between the ages of 7 and 15, overlapping the work of the gymnasium by three years, the latter extending between the ages of 12 and 19. Elementary work may be begun at the age of 6 years, and in such cases students may finish the gymnasium at 18. Twelve years of work lead to medicine, where six years of work are required, including preliminary courses in physics, chemistry and biology. The time required to complete the entire course is 18 years and the usual age at completion is 25.

Denmark.—Elementary education extends between the ages of 6 and 12, leading to the "laerdeskoler," the secondary schools which extend between the ages of 12 and 18, a total of 12 years. The medical course covers six years, including preliminary courses in the natural sciences. Time to complete the work is 18 years and the minimum age at completion is 24.

France.—Elementary education extends between the ages of 6 and 13 or 14. The majority of students entering the secondary schools, however, obtain their elementary work from tutors or in special preparatory courses connected with the lycées. The secondary school, the lycée, has a nine-year course divided into two cycles of five and four years, respectively, and extends between the ages of 11 and 18. From age 6, therefore, twelve years of training are required to complete the primary and secondary work. An additional year devoted to the natural sciences which must be taken in a college of science admits to the four-year medical course. Entire course therefore, is 17 years and the age at completion is 23.

Germany.—Elementary study extends between the ages of 6 and 14, overlapping the gymnasium by four years, the latter extending between the ages of 10 and 18. Then follows a six-year course, which includes preliminary courses in the natural sciences, and the last year must be spent in hospital work. This gives the right to practice, but additional work is required, and a severe examination, the "examen rigorosum," must be passed to secure the degree of doctor. Eighteen years of work lead to medical practice or 19 to the Doctorate, and the age at completion is at least 24 or 25.

Great Britain.—There appears to be no connection between elementary and secondary systems of education. Elementary public schools have been provided, extending between the ages of 6 and 12 or 15. Those entering secondary schools usually obtain their elementary instruction from private tutors or in the preparatory courses of the secondary schools. At present there are no public secondary schools in Great Britain, although that country abounds in private secondary schools, having courses varying as to age. Taking Rugby as an example, the course extends from the age of 10 to 17. Others extend from the age of 12 to 19. There are various ages at which the student may enter the medical schools, the minimum age fixed by the General Medical Council being 16. The time spent in elementary and secondary education, therefore, ranges from 10 to 13 years. Work must then be taken in physics, chemistry and biology either in a college of science or in the medical college as a part of the regular five-year medical course. Authorities agree that only a small proportion of students enter the medical school before the 18th year and few graduates in medicine before the age of 23. Since the promotion from one grade to another depends entirely on the passing of an examination, the time to complete the medical course usually requires six or more years.

Greece.—Elementary education is given in the "demotic" schools between the ages of 6 and 10 and in the "hellenic" schools between the ages of 10 and 14, leading to the secondary schools or gymnasia, which occupy the time between the ages of 14 and 18. Twelve years are occupied, therefore, by elementary and secondary education. Two years of work in the university devoted to botany, chemistry, physics, mineralogy, geology and zoology must be completed in order to begin the four-year medical course for the degree of Doctor. To secure the right to practice, nine months of postgraduate work in a hospital must be completed. The total time requirement is 19 years, and the minimum age at completion of the entire course is 25.

Hungary.—Elementary education extends between the ages of 6 and 12 years, overlapping secondary education, which extends between the ages of 10 and 18. The 12 years' work thus completed leads to the five-year medical course, which includes preliminary work in physics, chemistry and biology. The time for the entire course is therefore, 17 years and the minimum age at completion is 23.

Italy.—Elementary education is divided into lower elementary extending between the ages of 6 and 9 years and higher elementary extending between 9 and 12 years. Secondary education is given in the ginnasio, extending between the ages of 10 and 15 years and in the liceo which extends between the ages of 15 and 18 years. This is followed by a six-year course in medicine which includes work in the natural sciences. The complete course, therefore, is elementary study 4 years, ginnasio 5 years, liceo 3 years and medicine 6 years, a total of 18 years. The minimum age at completion of the course is 24 years.

Japan.—Ordinary elementary education extends between the ages of 6 and 10 years and higher elementary education is between the ages of 10 and 14 years, overlapping the work of the "middle school" by two years, the latter extending between the ages of 12 and 17 years. Completing the work of the middle school admits to the four-year medical course in all medical schools, except those at Tokio, Kioto and Fukuoka, which require also the completion of three years of higher preliminary education.

Netherlands.—Elementary education extends between the ages of 6 and 12 years, leading to the gymnasium, which extends from the 12th to the 18th year. Admission is then secured to the six-year medical course, which includes work in the natural sciences. The time to complete the entire course is 18 years and the minimum age is 24.

Norway.—Elementary education extends between the ages of 6 and 12 years, overlapping the secondary, which extends between the ages of 9 and 18 years. Secondary education is divided into a six-year middle school and a three-year gymnasium. The completion of the course of the gymnasium admits to the six-year medical course, which includes work in physics, chemistry and biology. The entire time, therefore, is 18 years and the minimum age at completion is 24. This gives the right to practice with the title of physician. The degree of Doctor requires extra work and the passing of special examinations.

Portugal.—Elementary education extends between the ages of 6 and 12 years, thus overlapping the work of the lyceum, which extends between the ages of 9 and 16. This is followed by a course of one or two years in a faculty of philosophy and mathematics and then five years in medicine for the degree of licentiate in medicine and a sixth year for the degree of Doc-

tor. The time for the entire course, therefore, is 18 years and the minimum age at completion is 24.

Russia.—Elementary education extends for 5 years between the ages of 6 and 11. Secondary education, as given in the gymnasium, extends over 7 years between the ages of 11 and 18. Completion of the secondary work admits to the 5-year medical course, which includes preliminary work in the natural sciences extending through the first two years along with other subjects. The total time is 17 years and the minimum age at completion is 23.

Spain.—Elementary education extends between the ages of 6 and 14 years, overlapping the work of the gymnasia, the secondary schools, which conduct work between the ages of 10 and 17. After completing the work of the gymnasium, one year of "preliminary study" must be taken, devoted to chemistry and natural science. Six years more gives the degree of licentiate in medicine and one more that of doctor. The complete course, therefore, requires 18 years of study and the minimum age at completion is 24.

Sweden.—Elementary education extends over 7 years between the ages of 6 and 13. Secondary education consists of a *five-year lower modern course and a four-year higher gymnasium*, the two courses being attended by students between the ages of 9 and 18. After completing the gymnasium, one year of preliminary work in the natural sciences must be taken in a college of philosophy. Seven years more of study gives the degree of licentiate in medicine, which carries with it the right *to practice. To secure the degree of Doctor* requires more work and the passing of special examinations. Promotion to each succeeding grade depends on the passing of an examination, and the medical course often extends to 9 or more years. The entire course, therefore, includes: elementary work, 3 years; lower modern school, 5 years; higher gymnasium, 4 years; college of philosophy, 1 year, and medicine, 7 years, a total of 20 years. The age at completion is 26 to 28 years.

Switzerland.—The Cantons differ somewhat in the length of their secondary courses, but all agree in regard to the preliminary work for admission to medicine and the length of the medical course. Taking the Canton of Zürich as an example, the elementary work extends over 6 years between the ages of 6 and 12. The secondary schools, known as gymnasia (realschulen or lycea), have courses covering seven years, students attending between the ages of 11 and 18. Graduation from the gymnasium admits to the five-year medical course, which includes preliminary courses in physics, chemistry and biology. The entire course, therefore, requires: elementary work, 5 years; gymnasium, 7 years, and medicine, 5 years, a total of 17 years. The minimum age at completion is 23. The degree of Doctor is not essential to practice, but may be obtained by writing a special thesis and taking certain courses without necessarily requiring a longer course.

Uruguay.—Elementary education extends between the ages of 6 and 14 years, leading to the secondary, which extends from the 14th to the 18th year. A six-year medical course follows, which includes preliminary work in physics, chemistry and biology. The time to complete the entire work is 18 years and the minimum age at completion is 24.

THE AMERICAN MEDICAL ASSOCIATION STANDARDS OF MEDICAL EDUCATION

These standards were suggested by the Council on Medical Education and the reports were adopted by the House of Delegates of the American Medical Association.

Standard [illegible] to

The minimum standard [illegible] the practice of medicine is as [illegible]

1. (a) The preliminary requi[illegible] school education or its equivalen[illegible] student to one of our recognized u[illegible] (after Jan. 1, 1910), a ye[illegible] months, devoted to the study of physics, chemistry, biology and one language (preferably German or French), to be taken either in a college of liberal arts or in a recognized medical college having a preliminary year devoted exclusively to the subjects mentioned.

2. There should be a requirement that previous to matriculation in a medical college every student must secure from the State Examining Board a "medical student's entrance certificate," which would be issued either on presentation of credentials of preliminary education not less than that laid down by requirement one, or on passing an examination given by the Board and which will satisfy the Board that the student has an equivalent education.

3. A medical training in a medical college, having four years of not less than thirty weeks each year, exclusive of holidays, of thirty hours per week of actual work.

4. Graduation from an approved medical college required to entitle the candidate to an examination before a state examining board.

5. The passing of a satisfactory examination before a state examining board.

The Ideal Standard

The ideal standard to be aimed at from the present viewpoint should consist of: (A) Preliminary education sufficient to enable the candidate to enter our recognized universities, such qualifications to be passed upon by the state authorities. (B) A course of at least one year to be devoted to physics, chemistry and biology, such arrangement to be made that this year could be taken either in a college of liberal arts or in the medical school. (C) Four years in pure medical work, the first two of which should be largely spent in laboratories of anatomy, physiology, pathology, pharmacology, etc., and the last two in close contact with patients in dispensaries and hospitals in the study of medicine, surgery, obstetrics, and the specialties. (D) A sixth year as an interne in a hospital or dispensary should then complete the medical course.

Under such a scheme the majority of men would begin the study of medicine between 18 and 19 years of age, and would graduate from the hospital interneship at from 24 to 25. A college education is recognized as a desirable preparation for a limited number of men, but [illegible] hought that it is not and never will be desirable to m[illegible] a college education a requirement to the study of m[illegible] as it would make the age of graduation from 27 to 2[illegible] regarded as too old a period [illegible] which the y[illegible] hould begin his life's work. [illegible] bvious [illegible] able scheme of requiremen[illegible] be [illegible] recommended.

Botany, with laboratory work	.5	1	2.5
Zoology, with laboratory work	.5	1	2.5
Physiology and Hygiene, with laboratory work	1	2	5
Group 7:			
Chemistry, with laboratory	1	2	5
Total	18	36	90

A *unit* is the credit value of 36 weeks' work of 5 recitation periods per week, each recitation period to be of not less than 45 minutes.

A *point* is the credit value of 18 weeks' work of 5 recitation periods per week, each recitation period to be of not less than 45 minutes.

A *count* is the credit of one recitation period per week of not less than 45 minutes through 36 weeks.

It is urged that within a reasonable time the minimum requirements as given in paragraph (b) will be enlarged to include an additional year or university physics, chemistry, biology and a reading knowledge of German or French.

B. Preliminary Examination.—The preliminary examination should be taken before the board of medical examiners or its authorized agent, and should represent the work of 15 units (30 points or credits or 75 counts) in accordance with the above outline. Under no circumstances must this examination be given by any one connected with the medical college.

Later, when the requirement is considered reasonable, university courses in physics, chemistry, biology and modern languages should be required in this examination.

2. Medical Education.—The medical college should give a strictly graded course covering four years of not less than thirty weeks each year, exclusive of holidays. Each year should cover not less than thirty hours per week of scheduled class room work in lectures, recitations, laboratory and clinical work. At least forty-two calendar months should elapse between the dates of matriculation and graduation. The complete course should approximate 3,600 hours and include:

(a) Two years of study, consisting largely of laboratory work in anatomy, histology, embryology, physiology, chemistry, pharmacology, physiologic chemistry, bacteriology and pathology.

(b) Two years of clinical work largely in hospitals and dispensaries, with thorough courses in internal medicine (including physical diagnosis, pediatrics, nervous and mental diseases), surgery (including surgical anatomy and operative surgery on the cadaver), obstetrics, gynecology, materia medica, pharmacology, laryngology, rhinology, ophthalmology, otology, dermatology, hygiene and medical jurisprudence. There should also be a laboratory course in clinical microscopy, including hematology, and the hospital courses should be accompanied by work in properly equipped clinical laboratories.

3. Advanced Standing.—(a) Advanced standing may be granted to the extent of three years of work taken at other recognized colleges.

(b) In giving advanced standing the college should not discriminate against its own full-course students. It is meant by this that students should not be given full standing when they come from colleges not giving equivalent courses.

(c) Before granting any advanced standing the dean or secretary of the school to which the student seeks admission should obtain from the corresponding officer of the school from which the student comes a full statement of his credentials, so far as preliminary and medical education is concerned, and the standing of the student in each course he has taken.

4. Graduation.—The medical college should require of each student before graduation:

(a) Compliance with the above given requirements of preliminary and medical education.

(b) An attendance of at least 80 per cent. on each course of instruction above mentioned.

(c) The passing of a final examination in each course of instruction above mentioned with a percentage of at least 75.

(d) The individual dissection of at least one lateral half of a human cadaver.

(e) The individual attendance on and management of at least two maternity cases.

(f) The work of at least the fourth or senior year must be taken in the medical college granting the degree.

II. EQUIPMENT AND FACILITIES

1. Buildings.—The medical college buildings should be well lighted, sanitary and commodious, with ample space for laboratories, amphitheaters, examining, lecture, recitation and special research rooms, as well as storage rooms and a suitable place for such animals as are used in experimental work.

2. Laboratories.—There should be well-equipped laboratories for practical anatomy, histology, embryology, physiology, chemistry, physiologic chemistry pharmacology, bacteriology and pathology, and these laboratories should be officered by trained instructors paid to devote their entire time to the preparation of materials used in instruction and to teaching and research. By a well-equipped laboratory is understood a laboratory provided with all the microscopes and other apparatus necessary to enable each student to carry on the work of that department intelligently and successfully.

3. Hospitals, Dispensaries and Clinical Facilities.—(a) The main hospital and dispensary should be in close proximity to the college building, of easy access to the students, and should be under the control of the college at least so far as clinical material is concerned.

(b) The hospital material available for clinical purposes should be in proportion to a daily average of at least 200 patients to 100 students in the senior class.

(c) The dispensary material should be carefully classified and properly used.

4. Library, Museum, Charts, Etc.—(a) Library: The medical college should have a working medical library, including the more recent text and reference books, as well as ten or more of the chief medical periodicals. This library room should be easily accessible, should be provided with suitable tables and chairs, and should have an attendant in charge.

(b) Museum: There should be a medical museum having its various anatomic, embryologic, pathologic and other specimens carefully prepared, labeled and indexed in order that any specimen may be easily found and employed for teaching purposes. The value of the pathologic collection could be greatly augmented by having slides showing the microscopic findings in each case carefully prepared, labeled, indexed and kept easily accessible. Clinical records of these cases should also be drawn up, indexed and filed for easy reference.

(c) Charts, Models, Stereopticons, Etc.—The medical college should have a supply of anatomic charts, embryologic models and other apparatus, such as a steropticon or a reflectoscope, as well as microphotographic, Roentgen ray or other apparatus, of service in the teaching of medicine.

(Continued on page 549)

tor. The time for the entire course, therefore, is 18 years and the minimum age at completion is 24.

Russia.—Elementary education extends for 5 years between the ages of 6 and 11. Secondary education, as given in the gymnasium, extends over 7 years between the ages of 11 and 18. Completion of the secondary work admits to the 5-year medical course, which includes preliminary work in the natural sciences extending through the first two years along with other subjects. The total time is 17 years and the minimum age at completion is 23.

Spain.—Elementary education extends between the ages of 6 and 14 years, overlapping the work of the gymnasia, the secondary schools, which conduct work between the ages of 10 and 17. After completing the work of the gymnasium, one year of "preliminary study" must be taken, devoted to chemistry and natural science. Six years more gives the degree of licentiate in medicine and one more that of doctor. The complete course, therefore, requires 18 years of study and the minimum age at completion is 24.

Sweden.—Elementary education extends over 7 years between the ages of 6 and 13. Secondary education consists of a five-year lower modern course and a four-year higher gymnasium, the two courses being attended by students between the ages of 9 and 18. After completing the gymnasium, one year of preliminary work in the natural sciences must be taken in a college of philosophy. Seven years more of study gives the degree of licentiate in medicine, which carries with it the right to practice. To secure the degree of Doctor requires more work and the passing of special examinations. Promotion to each succeeding grade depends on the passing of an examination, and the medical course often extends to 9 or more years. The entire course, therefore, includes: elementary work, 3 years; lower modern school, 5 years; higher gymnasium, 4 years; college of philosophy, 1 year, and medicine, 7 years, a total of 20 years. The age at completion is 26 to 28 years.

Switzerland.—The Cantons differ somewhat in the length of their secondary courses, but all agree in regard to the preliminary work for admission to medicine and the length of the medical course. Taking the Canton of Zürich as an example, the elementary work extends over 6 years between the ages of 6 and 12. The secondary schools, known as gymnasia (realschulen or lyçea), have courses covering seven years, students attending between the ages of 11 and 18. Graduation from the gymnasium admits to the five-year medical course, which includes preliminary courses in physics, chemistry and biology. The entire course, therefore, requires: elementary work, 5 years; gymnasium, 7 years, and medicine, 5 years, a total of 17 years. The minimum age at completion is 23. The degree of Doctor is not essential to practice, but may be obtained by writing a special thesis and taking certain courses without necessarily requiring a longer course.

Uruguay.—Elementary education extends between the ages of 6 and 14 years, leading to the secondary, which extends from the 14th to the 18th year. A six-year medical course follows, which includes preliminary work in physics, chemistry and biology. The time to complete the entire work is 18 years, and the minimum age at completion is 24.

THE AMERICAN MEDICAL ASSOCIATION STANDARDS OF MEDICAL EDUCATION

These standards were suggested by the Council on Medical Education and the reports were adopted by the House of Delegates of the American Medical Association.

Standard Now Recommended

The minimum standard now recommended prerequisite to the practice of medicine is as follows:

1. (a) The preliminary requirement to be a four-year high school education or its equivalent, such as would admit the student to one of our recognized universities; (b) and in addition (after Jan. 1, 1910), a year of not less than nine months, devoted to the study of physics, chemistry, biology and one language (preferably German or French), to be taken either in a college of liberal arts or in a recognized medical college having a preliminary year devoted exclusively to the subjects mentioned.

2. There should be a requirement that previous to matriculation in a medical college every student must secure from the State Examining Board a "medical student's entrance certificate," which would be issued either on presentation of credentials of preliminary education not less than that laid down by requirement one, or on passing an examination given by the Board and which will satisfy the Board that the student has an equivalent education.

3. A medical training in a medical college, having four years of not less than thirty weeks each year, exclusive of holidays, of thirty hours per week of actual work.

4. Graduation from an approved medical college required to entitle the candidate to an examination before a state examining board.

5. The passing of a satisfactory examination before a state examining board.

The Ideal Standard

The ideal standard to be aimed at from the present viewpoint should consist of: (A) Preliminary education sufficient to enable the candidate to enter our recognized universities, such qualifications to be passed upon by the state authorities. (B) A course of at least one year to be devoted to physics, chemistry and biology, such arrangement to be made that this year could be taken either in a college of liberal arts or in the medical school. (C) Four years in pure medical work, the first two of which should be largely spent in laboratories of anatomy, physiology, pathology, pharmacology, etc., and the last two in close contact with patients in dispensaries and hospitals in the study of medicine, surgery, obstetrics, and the specialties. (D) A sixth year as an interne in a hospital or dispensary should then complete the medical course.

Under such a scheme the majority of men would begin the study of medicine between 18 and 19 years of age, and would graduate from the hospital interneship at from 24 to 25. A college education is recognized as a desirable preparation for a limited number of men, but it is thought that it is not and never will be desirable to make such college education a requirement to the study of medicine, as it would make the age of graduation from 27 to 28 years, which is regarded as too old a period at which the young medical man should begin his life's work. It is obvious that this very desirable scheme of requirements can not be at once demanded or recommended.

A Medical College in Good Standing

Below is a schedule of the minimum requirements, laboratory equipment and clinical facilities which should obtain in a medical college before it can be considered as giving a satisfactory course or be determined as a medical college in good standing:

I. REQUIREMENTS

1. *Matriculation.*—For matriculation the medical college should require of each student:

(1) A certificate of good moral character, signed by two reputable physicians of the state in which the applicant resides; and,

(2) As evidence of satisfactory preliminary education, a *medical student's matriculation certificate*, issued by the state board of medical examiners or its authorized agent, this certificate to be issued on (A) acceptable credentials, or (B) on successfully passing a preliminary examination.

A. Acceptable Credentials.—(a) A degree from an accredited university or college of arts or science; or,

(b) A diploma from an accredited four-year high school, normal school or academy which required for admission eight years of study in the primary and intermediate grades and which furnished a preliminary education of at least 15 units (30 points or credits, or 75 counts), as given in the following outline (suggested by Dr. W. J. Means, a member of the Council's committee and also chairman of the Judicial Council of the Association of American Medical Colleges):

REQUIRED BRANCHES.

	Units.	Points.	Counts.
Rhetoric and composition	1	2	5
History of English and American literature	1	2	5
Algebra through graduates	1	2	5
Geometry, plane	1	2	5
Latin, grammar and 4 books of Cæsar or equivalent	2	4	10
U. S. History and Civics	1	2	5
Physics, with laboratory work	1	2	5
Total	8	16	40

ELECTIVE BRANCHES.

Seven units, 14 points or credits, or 35 counts to be selected from the following subjects. Not more than 2 units, 4 points or credits or 10 counts from any one group:

	Units.	Points.	Counts.
Group 1:			
English Classics (College Entrance Examining Board list)	2	4	10
Group 2:			
Geometry, solid	.5	1	2.5
Trigonometry	.5	1	2.5
Group 3:			
Latin, Cicero (7 orations)	1	2	5
Latin, Virgil (6 books)	1	2	5
Group 4:			
German, grammar with 2 years' certified work	2	4	10
French, grammar with 2 years' certified work	2	4	10
Spanish, grammar with 2 years' certified work	2	4	10
Group 5:			
History, Greece and Rome	1	2	5
History, medieval and modern	1	2	5
History, England, half years' work	.5	1	2.5
History, France, half years' work	.5	1	2.5
Group 6:			
Biology, with laboratory work	1	2	5
Botany, with laboratory work	.5	1	2.5
Zoology, with laboratory work	.5	1	2.5
Physiology and Hygiene, with laboratory work	1	2	5
Group 7:			
Chemistry, with laboratory	1	2	5
Total	18	36	90

A *unit* is the credit value of 36 weeks' work of 5 recitation periods per week, each recitation period to be of not less than 45 minutes.

A *point* is the credit value of 18 weeks' work of 5 recitation periods per week, each recitation period to be of not less than 45 minutes.

A *count* is the credit of one recitation period per week of not less than 45 minutes through 36 weeks.

It is urged that within a reasonable time the minimum requirements as given in paragraph (b) will be enlarged to include an additional year or university physics, chemistry, biology and a reading knowledge of German or French.

B. Preliminary Examination.—The preliminary examination should be taken before the board of medical examiners or its authorized agent, and should represent the work of 15 units (30 points or credits or 75 counts) in accordance with the above outline. Under no circumstances must this examination be given by any one connected with the medical college.

Later, when the requirement is considered reasonable, university courses in physics, chemistry, biology and modern languages should be required in this examination.

2. Medical Education.—The medical college should give a strictly graded course covering four years of not less than thirty weeks each year, exclusive of holidays. Each year should cover not less than thirty hours per week of scheduled class room work in lectures, recitations, laboratory and clinical work. At least forty-two calendar months should elapse between the dates of matriculation and graduation. The complete course should approximate 3,600 hours and include:

(a) Two years of study, consisting largely of laboratory work in anatomy, histology, embryology, physiology, chemistry, pharmacology, physiologic chemistry, bacteriology and pathology.

(b) Two years of clinical work largely in hospitals and dispensaries, with thorough courses in internal medicine (including physical diagnosis, pediatrics, nervous and mental diseases), surgery (including surgical anatomy and operative surgery on the cadaver), obstetrics, gynecology, materia medica, pharmacology, laryngology, rhinology, ophthalmology, otology, dermatology, hygiene and medical jurisprudence. There should also be a laboratory course in clinical microscopy, including hematology, and the hospital courses should be accompanied by work in properly equipped clinical laboratories.

3. Advanced Standing.—(a) Advanced standing may be granted to the extent of three years of work taken at other recognized colleges.

(b) In giving advanced standing the college should not discriminate against its own full-course students. It is meant by this that students should not be given full standing when they come from colleges not giving equivalent courses.

(c) Before granting any advanced standing the dean or secretary of the school to which the student seeks admission should obtain from the corresponding officer of the school from which the student comes a full statement of his credentials, so far as preliminary and medical education is concerned, and the standing of the student in each course he has taken.

4. Graduation.—The medical college should require of each student before graduation:

(a) Compliance with the above given requirements of preliminary and medical education.

(b) An attendance of at least 80 per cent. on each course of instruction above mentioned.

(c) The passing of a final examination in each course of instruction above mentioned with a percentage of at least 75.

(d) The individual dissection of at least one lateral half of a human cadaver.

(e) The individual attendance on and management of at least two maternity cases.

(f) The work of at least the fourth or senior year must be taken in the medical college granting the degree.

II. EQUIPMENT AND FACILITIES

1. Buildings.—The medical college buildings should be well lighted, sanitary and commodious, with ample space for laboratories, amphitheaters, examining, lecture, recitation and special research rooms, as well as storage rooms and a suitable place for such animals as are used in experimental work.

2. Laboratories.—There should be well-equipped laboratories for practical anatomy, histology, embryology, physiology, chemistry, physiologic chemistry pharmacology, bacteriology and pathology, and these laboratories should be officered by trained instructors paid to devote their entire time to the preparation of materials used in instruction and to teaching and research. By a well-equipped laboratory is understood a laboratory provided with all the microscopes and other apparatus necessary to enable each student to carry on the work of that department intelligently and successfully.

3. Hospitals, Dispensaries and Clinical Facilities.—(a) The main hospital and dispensary should be in close proximity to the college building, of easy access to the students, and should be under the control of the college at least so far as clinical material is concerned.

(b) The hospital material available for clinical purposes should be in proportion to a daily average of at least 200 patients to 100 students in the senior class.

(c) The dispensary material should be carefully classified and properly used.

4. Library, Museum, Charts, Etc.—(a) Library: The medical college should have a working medical library, including the more recent text and reference books, as well as ten or more of the chief medical periodicals. This library room should be easily accessible, should be provided with suitable tables and chairs, and should have an attendant in charge.

(b) Museum: There should be a medical museum having its various anatomic, embryologic, pathologic and other specimens carefully prepared, labeled and indexed in order that any specimen may be easily found and employed for teaching purposes. The value of the pathologic collection could be greatly augmented by having slides showing the microscopic findings in each case carefully prepared, labeled, indexed and kept easily accessible. Clinical records of these cases should also be drawn up, indexed and filed for easy reference.

(c) Charts, Models, Stereopticons, Etc.—The medical college should have a supply of anatomic charts, embryologic models and other apparatus, such as a steropticon or a reflectoscope, as well as microphotographic, Roentgen ray or other apparatus, of service in the teaching of medicine.

(Continued on page 549)

tor. The time for the entire course, therefore, is 18 years and the minimum age at completion is 24.

Russia.—Elementary education extends for 5 years between the ages of 6 and 11. Secondary education, as given in the gymnasium, extends over 7 years between the ages of 11 and 18. Completion of the secondary work admits to the 5-year medical course, which includes preliminary work in the natural sciences extending through the first two years along with other subjects. The total time is 17 years and the minimum age at completion is 23.

Spain.—Elementary education extends between the ages of 6 and 14 years, overlapping the work of the gymnasia, the secondary schools, which conduct work between the ages of 10 and 17. After completing the work of the gymnasium, one year of "preliminary study" must be taken, devoted to chemistry and natural science. Six years more gives the degree of licentiate in medicine and one more that of doctor. The complete course, therefore, requires 18 years of study and the minimum age at completion is 24.

A six-year medical course follows, which includes preliminary work in physics, chemistry and biology. The time to complete the entire work is 18 years, and the minimum age at completion is 24.

THE AMERICAN MEDICAL ASSOCIATION STANDARDS OF MEDICAL EDUCATION

These standards were suggested by the Council on Medical Education and the reports were adopted by the House of Delegates of the American Medical Association.

Standard Now Recommended

The minimum standard now recommended prerequisite to the practice of medicine is as follows:

1. (a) The preliminary requirement to be a four-year high school education or its equivalent, such as would admit the student to one of our recognized universities; (b) and in addition (after Jan. 1, 1910), a year of not less than nine months, devoted to the study of physics, chemistry, biology and one language (preferably German or French), to be taken either in a college of liberal arts or in a recognized medical college having a preliminary year devoted exclusively to the subjects mentioned.

2. There should be a requirement that previous to matriculation in a medical college every student must secure from the State Examining Board a "medical student's entrance certificate," which would be issued either on presentation of credentials of preliminary education not less than that laid down by requirement one, or on passing an examination given by the Board and which will satisfy the Board that the student has an equivalent education.

3. A medical training in a medical college, having four years of not less than thirty weeks each year, exclusive of holidays, of thirty hours per week of actual work.

4. Graduation from an approved medical college required to entitle the candidate to an examination before a state examining board.

5. The passing of a satisfactory examination before a state examining board.

The Ideal Standard

The ideal standard to be aimed at from the present viewpoint should consist of: (A) Preliminary education sufficient to enable the candidate to enter our recognized universities, such qualifications to be passed upon by the state authorities. (B) A course of at least one year to be devoted to physics, chemistry and biology, such arrangement to be made that this year could be taken either in a college of liberal arts or in the medical school. (C) Four years in pure medical work, the first two of which should be largely spent in laboratories of anatomy, physiology, pathology, pharmacology, etc., and the last two in close contact with patients in dispensaries and hospitals in the study of medicine, surgery, obstetrics, and the specialties. (D) A sixth year as an interne in a hospital or dispensary should then complete the medical course.

Under such a scheme the majority of men would begin the study of medicine between 18 and 19 years of age, and would graduate from the hospital interneship at from 24 to 25. A college education is recognized as a desirable preparation for a limited number of men, but it is thought that it is not and never will be desirable to make such college education a requirement to the study of medicine, as it would make the age of graduation from 27 to 28 years, which is regarded as too old a period at which the young medical man should begin his life's work. It is obvious that this very desirable scheme of requirements can not be at once demanded or recommended.

A Medical College in Good Standing

Below is a schedule of the minimum requirements, laboratory equipment and clinical facilities which should obtain in a medical college before it can be considered as giving a satisfactory course or be determined as a medical college in good standing:

I. REQUIREMENTS

1. Matriculation.—For matriculation the medical college should require of each student:

(1) A certificate of good moral character, signed by two reputable physicians of the state in which the applicant resides; and,

(2) As evidence of satisfactory preliminary education, a medical student's matriculation certificate, issued by the state board of medical examiners or its authorized agent, this certificate to be issued on (A) acceptable credentials, or (B) on successfully passing a preliminary examination.

A. Acceptable Credentials.—(a) A degree from an accredited university or college of arts or science; or,

(b) A diploma from an accredited four-year high school, normal school or academy which required for admission eight years of study in the primary and intermediate grades and which furnished a preliminary education of at least 15 units (30 points or credits, or 75 counts), as given in the following outline (suggested by Dr. W. J. Means, a member of the Council's committee and also chairman of the Judicial Council of the Association of American Medical Colleges):

REQUIRED BRANCHES.

	Units.	Points.	Counts.
Rhetoric and composition	1	2	5
History of English and American literature	1	2	5
Algebra through graduates	1	2	5
Geometry, plane	1	2	5
Latin, grammar and 4 books of Cæsar or equivalent	2	4	10
U. S. History and Civics	1	2	5
Physics, with laboratory work	1	2	5
Total	8	16	40

ELECTIVE BRANCHES.

Seven units, 14 points or credits, or 35 counts to be selected from the following subjects. Not more than 2 units, 4 points or credits or 10 counts from any one group:

	Units.	Points.	Counts.
Group 1:			
English Classics (College Entrance Examining Board list)	2	4	10
Group 2:			
Geometry, solid	.5	1	2.5
Trigonometry	.5	1	2.5
Group 3:			
Latin, Cicero (7 orations)	1	2	5
Latin, Virgil (6 books)	1	2	5
Group 4:			
German, grammar with 2 years' certified work	2	4	10
French, grammar with 2 years' certified work	2	4	10
Spanish, grammar with 2 years' certified work	2	4	10
Group 5:			
History, Greece and Rome	1	2	5
History, medieval and modern	1	2	5
History, England, half years' work	.5	1	2.5
History, France, half years' work	.5	1	2.5
Group 6:			
Biology, with laboratory work	1	2	5
Botany, with laboratory work	.5	1	2.5
Zoology, with laboratory work	.5	1	2.5
Physiology and Hygiene, with laboratory work	1	2	5
Group 7:			
Chemistry, with laboratory	1	2	5
Total	18	36	90

A *unit* is the credit value of 36 weeks' work of 5 recitation periods per week, each recitation period to be of not less than 45 minutes.

A *point* is the credit value of 18 weeks' work of 5 recitation periods per week, each recitation period to be of not less than 45 minutes.

A *count* is the credit of one recitation period per week of not less than 45 minutes through 36 weeks.

It is urged that within a reasonable time the minimum requirements as given in paragraph (b) will be enlarged to include an additional year or university physics, chemistry, biology and a reading knowledge of German or French.

B. Preliminary Examination.—The preliminary examination should be taken before the board of medical examiners or its authorized agent, and should represent the work of 15 units (30 points or credits or 75 counts) in accordance with the above outline. Under no circumstances must this examination be given by any one connected with the medical college.

Later, when the requirement is considered reasonable, university courses in physics, chemistry, biology and modern languages should be required in this examination.

2. Medical Education.—The medical college should give a strictly graded course covering four years of not less than thirty weeks each year, exclusive of holidays. Each year should cover not less than thirty hours per week of scheduled class room work in lectures, recitations, laboratory and clinical work. At least forty-two calendar months should elapse between the dates of matriculation and graduation. The complete course should approximate 3,600 hours and include:

(a) Two years of study, consisting largely of laboratory work in anatomy, histology, embryology, physiology, chemistry, pharmacology, physiologic chemistry, bacteriology and pathology.

(b) Two years of clinical work largely in hospitals and dispensaries, with thorough courses in internal medicine (including physical diagnosis, pediatrics, nervous and mental diseases), surgery (including surgical anatomy and operative surgery on the cadaver), obstetrics, gynecology, materia medica, pharmacology, laryngology, rhinology, ophthalmology, otology, dermatology, hygiene and medical jurisprudence. There should also be a laboratory course in clinical microscopy, including hematology, and the hospital courses should be accompanied by work in properly equipped clinical laboratories.

3. Advanced Standing.—(a) Advanced standing may be granted to the extent of three years of work taken at other recognized colleges.

(b) In giving advanced standing the college should not discriminate against its own full-course students. It is meant by this that students should not be given full standing when they come from colleges not giving equivalent courses.

(c) Before granting any advanced standing the dean or secretary of the school to which the student seeks admission should obtain from the corresponding officer of the school from which the student comes a full statement of his credentials, so far as preliminary and medical education is concerned, and the standing of the student in each course he has taken.

4. Graduation.—The medical college should require of each student before graduation:

(a) Compliance with the above given requirements of preliminary and medical education.

(b) An attendance of at least 80 per cent. on each course of instruction above mentioned.

(c) The passing of a final examination in each course of instruction above mentioned with a percentage of at least 75.

(d) The individual dissection of at least one lateral half of a human cadaver.

(e) The individual attendance on and management of at least two maternity cases.

(f) The work of at least the fourth or senior year must be taken in the medical college granting the degree.

II. EQUIPMENT AND FACILITIES

1. Buildings.—The medical college buildings should be well lighted, sanitary and commodious, with ample space for laboratories, amphitheaters, examining, lecture, recitation and special research rooms, as well as storage rooms and a suitable place for such animals as are used in experimental work.

2. Laboratories.—There should be well-equipped laboratories for practical anatomy, histology, embryology, physiology, chemistry, physiologic chemistry pharmacology, bacteriology and pathology, and these laboratories should be officered by trained instructors paid to devote their entire time to the preparation of materials used in instruction and to teaching and research. By a well-equipped laboratory is understood a laboratory provided with all the microscopes and other apparatus necessary to enable each student to carry on the work of that department intelligently and successfully.

3. Hospitals, Dispensaries and Clinical Facilities.—(a) The main hospital and dispensary should be in close proximity to the college building, of easy access to the students, and should be under the control of the college at least so far as clinical material is concerned.

(b) The hospital material available for clinical purposes should be in proportion to a daily average of at least 200 patients to 100 students in the senior class.

(c) The dispensary material should be carefully classified and properly used.

4. Library, Museum, Charts, Etc.—(a) Library: The medical college should have a working medical library, including the more recent text and reference books, as well as ten or more of the chief medical periodicals. This library room should be easily accessible, should be provided with suitable tables and chairs, and should have an attendant in charge.

(b) Museum: There should be a medical museum having its various anatomic, embryologic, pathologic and other specimens carefully prepared, labeled and indexed in order that any specimen may be easily found and employed for teaching purposes. The value of the pathologic collection could be greatly augmented by having slides showing the microscopic findings in each case carefully prepared, labeled, indexed and kept easily accessible. Clinical records of these cases should also be drawn up, indexed and filed for easy reference.

(c) Charts, Models, Stereopticons, Etc.—The medical college should have a supply of anatomic charts, embryologic models and other apparatus, such as a steropticon or a reflectoscope, as well as microphotographic, Roentgen ray or other apparatus, of service in the teaching of medicine.

REFERENCES TO TABLE 1

Heavy faced figures show totals by states.

* Night schools. ** No tuition is charged.

† Colleges giving only the first two years of the medical course.

(a) Now the Leland Stanford Junior University College of Medicine.

(b) Now the Los Angeles Medical Department of the University of California.

(c) For non-residents of Kansas the fees for each of the first two years are $70.

(d) The number of graduates given includes eight post-graduates.

(e) For non residents of Michigan the total fees for each of the four years respectively are $130, $105, $105 and $35.

(f) Closed by the Board of Regents of the University of Minnesota, an elective chair each in materia medica and therapeutics in the College of Medicine and Surgery being substituted.

(g) Classes of 1910, 1911 and possibly 1912 will complete their work in the University of Minnesota College of Medicine and Surgery, but will obtain their degrees from Hamline University.

(h) These colleges have been suspended.

(i) These colleges have merged, forming the Ohio-Miami Medical College of the University of Cincinnati.

(j) The expenses of scholarship students including transportation, tuition and board are borne by the government.

(k) Number of students approximate; graduates given for 1908.

(l) These colleges have just merged, forming the Medical Department of the Universities of Nashville and Tennessee.

(m) Will be suspended after the close of the present session.

(n) Fees for non-residents of West Virginia are $50 per year.

(o) Non-residents of Wisconsin pay an additional fee of $50 per year.

(p) Total fees for the fifth year in the Canadian colleges are the same as for the fourth year.

(Continued from page 545)

III. CONDUCT OF THE COLLEGE.

1. The medical college should literally observe its published requirements for admission, tuition, time of attendance on the session and graduation, which it should definitely set forth, together with complete lists of its matriculates and annual graduates, in regular annual catalogues or announcements.

2. New medical colleges may be recognized on application if on examination they are found to comply with the above requirements.

THE ASSOCIATION OF AMERICAN MEDICAL COLLEGES

The requirements for admission to and graduation from colleges holding membership are as follows:

Preliminary Education: (*a*) A bachelor's degree from an approved college or university. (*b*) A diploma from an accredited high school, normal school or academy requiring for admission evidence of the completion of an eight-year course in primary and intermediate grades, and for graduation not less than four years of study embracing not less than two years (4 points) of Latin, two years (four points) of mathematics, two years (4 points) of English, one year (2 points) of history, one year (2 points) of physics, and six years (12 points) of further credit in language, literature, history or science (*c*) An examination in the following branches totaling 30 points: A. Required. (16 points): Mathematics (4 points), English (4 points), History (2 points), Latin (4 points), Physics (2 points).

B. Elective (14 points): English, language and literature, 4 points; language, German, French, Spanish, or Greek, in each not less than 2 points; solid geometry and trigonometry (½ year each), 2 points; biology (one year) or botany and zoology (½ year each), 2 points; chemistry (1 year), 2 points; physical geography and geology (½ year each), 1 point; physiology and hygiene (½ year each), 1 point; astronomy (½ year), 1 point; drawing (½ year), 1 point. One point in any subject in a high school or academic course demands not less than five periods per week of forty-five minutes each for eighteen weeks. (*d*) Certificates from reputable instructors recognized by any state board of medical examiners duly authorized by law or by the superintendents of public instruction in states having no board of examination, may be accepted in lieu of any part of this examination. (*e*) This examination must be conducted by or under the authority of the board of examiners or of the superintendent of public instruction of the city or state in which the college is located as provided for in subsection (*d*). In no case shall it be conducted by any person connected with the faculty, medical or otherwise, of the institution to which the student is seeking admission.

A student may be allowed to enter on his medical work conditioned in not more than six points, and these conditions must be removed by satisfactory examination before he is allowed to enter on the second year of his medical course.

Advanced Standing: Colleges in membership in this Association may honor the official credentials presented by students from other colleges having the standard requirements maintained by members of this Association, excepting for the fourth year of their course, but no member shall admit a student to advanced standing without first communicating with the college from which such student desires to withdraw, and receiving from the dean of such college a direct written communication certifying to the applicant's professional and moral qualifications, and to the exact work he had done in said college.

(Continued from page 549)

years, each annual course to have been of not less than thirty teaching weeks' duration, and at least ten months shall intervene between the beginning of any course and the beginning of the preceding course. No time credit shall be given to holders of a Bachelor's degree, but subject credit may be given on satisfactory examination. Four years of residence in a medical college shall be required of all candidates for the degree of doctor of medicine.

The entire course of four years shall consist of at least 4,000 hours, divided into the subjects as shown in the opposite table, and no college shall be recognized that falls below this standard over 20 per cent. in any one branch or over 10 per cent. in the total. Laboratory or clinic hours may be substituted for didactic hours.

Each student shall be obliged to attend 80 per cent. of the exercises in every annual course of study for which he seeks credit. No student shall be given credit on examination unless he attains a grade of at least 70 per cent., or its equivalent, in any other marking system. And no student shall be graduated unless he shall have attained a passing grade in each and all subjects of the required curriculum.

A college which gives less than a four years' course of study, but does not graduate students, and is possessed of other required qualifications, may be admitted to membership.

Each medical college in membership in the Association shall print in every annual catalogue or announcement a table of the total number of hours work given in said college, arranged both by subjects and years.

The following colleges are members of the association: College of Physicians and Surgeons, Los Angeles, Cal.; Leland Stanford Junior University College of Medicine, Palo Alto and San Francisco, Cal.; University of California, Medical Department, Berkeley, Los Angeles, and San Francisco, Cal.; University of Colorado, School of Medicine, Boulder, Colo.; Denver and Gross College of Medicine, Denver, Colo.; George Washin

Ohio: Western Reserve Cleveland, Ohio; Starling-Ohio Medical State University of Oklahoma School of Meharry Medical College, Nashville, Ten Medical Department, Nashville, Tenn.: Richmond, Va.; University College of Medicine, Richmond, Va.; University of West Virginia Medical Department, Morgantown, W. Va.; Marquette University Medical Department, Milwaukee, Wis.; *University of Wisconsin* College of Medicine, Madison, Wis.

The secretary-treasurer of the Association is Dr. *Fred C.* Zapffe, 1764 Lexington street, Chicago.

SOUTHERN MEDICAL COLLEGE ASSOCIATION

The following requirements for admission to the freshman year are exacted by the colleges belonging to this Association:

The student must possess a diploma of graduation from some literary or scientific institution of learning, or a certificate that he has passed the entrance examination to a university, or a certificate from some legally constituted high school. The minimum preliminary education required by the Southern Medical College Association is a grammar school education and two years' successful attendance at a *recognized preparatory school* or a high school, or its equivalent, said equivalent to be determined by a superintendent of public instruction. A student may be given one month from date of his admission to submit his certificate of qualification. And if he fails to possess the requisite educational qualifications in one or more branches, he may matriculate and attend his first course of lectures, but must present the requisite certificate before matriculating in the second course, and all tickets or certificates in such cases must have the *conditions printed plainly on the face of each.* Beginning with the session of 1910-11 nothing less will be accepted than a diploma from an accredited high school as published in the catalogue of each state university, or its equivalent, such equivalent to be determined by the county or state superintendent of public instruction.

Colleges belonging to this Association are not to issue certificates of credit to any student who has not been in actual attendance on at least 80 per cent. of a seven months' medical course, nor to allow advanced standing on credentials representing less than that amount of work. No student is to be allowed to graduate unless he has been in actual attendance on at least 80 per cent. of a seven months' session immediately preceding said graduation.

The following colleges are members:

Medical College of Alabama, Mobile, Ala.; Birmingham Medical College, Birmingham, Ala.; Medical Department University of Arkansas, Little Rock, Ark.; College of Physicians and Surgeons, Little Rock, Ark.; Atlanta College of Physicians and Surgeons, Atlanta, Ga.; Medical College of Georgia, Augusta, Ga.; Medical Department, University of Mississippi, Oxford, Miss.; Medical Department, Epworth University, Oklahoma, Okla.; Medical Department, University of Tennessee, Nashville, Tenn.; Medical Department, University of Nashville, Nashville, Tenn.; Memphis Hospital Medical College, Memphis, Tenn.; Chattanooga Medical College, Chattanooga, Tenn.; Tennessee Medical College, Knoxville, Tenn.; Medical Department, Fort Worth University, Fort Worth, Texas; Medical Department, Baylor University, Dallas, Texas; Medical Department, Southwestern University, Dallas, Texas.

The secretary-treasurer is Dr. Lewis C. Morris, Birmingham, Ala.

AMERICAN INSTITUTE OF HOMEOPATHY

The minimum requirements for entrance into the freshman class of all homeopathic medical colleges, as adopted in 1901, are, with abbreviation, as follows:

1. English Composition.—Exercise on assigned theme, not less than 200 words. Exercise in reading. Exercise in correction of ungrammatical sentences.

2. Mathematics.—Arithmetical exercises in (a) vulgar fractions, (b) decimals, (c) percentage, (d) proportion, (e) square and cube root, (f) weights and measures, (g) decimal system. Mensuration—(a) Definition of terms, (b) exercises under the more fundamental rules.

3. Geography.—General facts about North America.

4. History.—General, with particular reference to human progress in art, science and letters. (The examination to avoid exact dates and minor details.)

5. Latin Language.—(a) Grammar, (b) four books of Cæsar or its equivalent.

The colleges recognized as in good standing by this organization are:

Hahnemann Medical College of the Pacific, San Francisco, Cal.; Denver College of Physicians and Surgeons, Denver, Colo.; Hahne-

(Continued on page 555)

mann Medical College, Chicago.; Hering Medical College; Homeopathic Medical Department of the State [illegible] western Homeopath [illegible] School of Medicine [illegible] Michigan; Detroit [illegible] Medical College; New York Homeopathic Medical College; New York Medical College for Women; Cleveland Homeopathic Medical College; Pulte Medical College, Cincinnati; Hahnemann Medical College of Philadelphia.

The secretary is Dr. J. Richey Horner, 655 Rose Bldg., Cleveland, Ohio.

NATIONAL CONFEDERATION OF ECLECTIC MEDICAL COLLEGES

The following are the present minimum requirements for admission to colleges members of this Association:

1. A certificate of good moral character.
2. Diploma of graduation from (a) a four years graded high school, or (b) normal school, or (c) seminary, or (d) literary or scientific college, or (e) university, or (f) evidence of having passed the matriculation examination to a recognized literary or scientific college, or (g) a medical student's certificate secured by examination from a state medical board.

The following colleges are members of this Association:

American Medical College, St. Louis, Mo.; California Eclectic Medical College, Los Angeles, Cal.; Eclectic Medical College of the City of New York, New York, N. Y.; Eclectic Medical Institute, Cincinnati, Ohio; Georgia College of Eclectic Medicine and Surgery, Atlanta, Ga.; Lincoln Medical College, Lincoln, Neb.; Western Eclectic College of Medicine and Surgery, Kansas City, Kan.

The secretary-treasurer is John K. Scudder, M.D., 1009 Plum street, Cincinnati, Ohio.

COLLEGE NOTES

New Colleges.—Besides the two new colleges formed by mergers, one new college was organized at Atlanta, Georgia, the Hospital Medical College, Eclectic.

Colleges Discontinued.—Besides the six colleges which have lost their identity through mergers during the past year, four colleges have been suspended. These are the College of Homeopathic Medicine of the University of Minnesota, abolished by the Board of Regents, the Homeopathic Medical College of Missouri of St. Louis, the Nebraska College of Medicine of Lincoln, and the College of Physicians and Surgeons of Dallas, Texas. The Medical Department of the University of the South will be discontinued after Oct. 28, 1909.

Statistics of Canadian Colleges.—Statistics of the eight Canadian medical colleges are given in the last eight lines of Table I. There were 1,755 medical students, including 24 women students and 346 graduates, including 4 women. Seventy-six, or 22 per cent. of all graduates were reported also to hold degrees in arts or science. This percentage is doubtless somewhat low since complete reports were not obtained in this respect from the University of Toronto. All the Canadian schools give courses of five years, this standard now being required for license in some of the Canadian provinces.

Colleges Merged.—During the past year mergers have taken place in four instances. At Cincinnati, the Medical College of Ohio and the Miami Medical College, completed their union, forming the Ohio-Miami Medical College of the University of Cincinnati. At Nashville, the University of Nashville Medical Department and the University of Tennessee Department of Medicine have united, the new school to be known as the Universities of Nashville and Tennessee Medical Department. The Keokuk Medical College, College of Physicians and Surgeons, Keokuk, Iowa, was absorbed by Drake University College of Medicine of Des Moines. The University of Southern California College of Medicine of Los Angeles was taken over by the University of California and will be operated as the Los Angeles medical department.

Confusion of Titles.—At the last meeting of the Association of American Universities, an effort was made to bring about a uniformity in the use of the terms "department," "course," "college," and "school" in the titles of educational institutions so as to have a definite meaning for each. The committee which was appointed to take up the matter made the following recommendations:

1. That the term *department* be restricted to the various subjects taught in the university; as, for instance, the department of Latin, department of mathematics, department of physics, etc.

2. That the term *course* be restricted to the subdivisions of a subject; as, for instance, course in English.

3. That the term *college* be restricted to a part of the university the standard of admission to which is the equivalent of that required by the Carnegie Foundation for the Advancement of Teaching and which offers instruction leading to a first degree in arts, letters or sciences.

4. That the term *school* be restricted to a part of the university, the standard of admission to which is not less than the equivalent of two-years' work in the college and which offers instruction of not less than two-years' duration leading to a technical or professional degree.

Higher Preliminary Requirements.—Seventeen medical colleges already require two or more years of collegiate work for admission in addition to a four year high school education. These colleges and the years when such requirement began are as follows:

College	Began
Johns Hopkins University Medical Department	1893
Harvard Medical School	1900
Western Reserve University, Medical Department	1901
University of Chicago, Rush Medical College	1904
University of California, Medical Department	1905
University of Minnesota, Coll. of Med. and Surg	1907
University of North Dakota, College of Medicine	1907
[illegible] n, College of Medicine	1907
[illegible] ical College	1908
[illegible] School of Medicine	1908
[illegible] University, Department of Medicine	1909
[illegible]	1909
*Northwestern University Medical School	1909
*University of Kansas, School of Medicine	1909
University of Michigan, College of Medicine	1909
*University of Nebraska, College of Medicine	1909
University of South Dakota, College of Medicine	1909

*One year required for the session of 1908-9.

Eleven other colleges have definitely announced an increase in their entrance requirements to two years of collegiate work. These and the dates when such requirements will become effective are as follows:

College	Begins
University of Colorado, School of Medicine	1910
*Indiana University School of Medicine	1910
*State University of Iowa, College of Medicine	1910
Drake University, College of Medicine	1910
†University of Missouri, Department of Medicine	1910
John A. Creighton Medical College	1910
Dartmouth Medical School	1910
Columbia University, College of Physicians and Surgeons	1910
*Syracuse University, College of Medicine	1910
*University of Pennsylvania, Medical Department	1910
*University of Utah, Medical Department	1910

*One year required for the session of 1909-10.
†One year has been required since 1906.

The twenty-one following colleges either already require one year of work in a college of liberal arts in addition to a four-year high school course, or have announced their intention to do so on or before the year given:

College	In Force
[illegible] hool of Medicine	1908
[illegible] rolina, Medical Department	1909
[illegible] licine and Surgery	1910
[illegible] ge of Medicine	1910
[illegible] d Surgeons, Chicago	1910
[illegible] llege, Chicago	1910
[illegible]	1910
[illegible] ouisiana, Medical Department	1910
St. Louis University School of Medicine	1910
[illegible] Medical Department	1910
[illegible] ti, Medical Department	1910
[illegible] College	1910
[illegible] hysicians and Surgeons	1910
[illegible] School of Medicine	1910
University of Oregon, Medical Department	1910
Vanderbilt University, Medical Department	1910
University of Texas, Medical Department	1910
*University of Virginia, Department of Medicine	1910
West Virginia University, College of Medicine	1910
Marquette University Medical Department	1910
Wisconsin College of Physicians and Surgeons	1910

*Requires a three-year high school course plus one year of college work.

Several other colleges were previously listed as having adopted higher requirements. A few have since rescinded their action, six have merged into other colleges, and others, on inspection, being found unsatisfactory, were omitted from the lists. The schools above named, however, have made definite statements regarding the increase in their entrance requirements and doubtless mean what they say.

SATURDAY, AUGUST 14, 1909

MEDICAL EDUCATION IN THE UNITED STATES

STATISTICS FOR THE COLLEGE YEAR 1908-9

The tabulated statistics herewith presented (pages 546 to 554) are for the year ending June 30, 1909, and are based on signed reports received directly from the medical colleges, or from other reliable sources. We wish here to acknowledge the courtesy and cooperation of the officials of the medical colleges which have made the compilation of these complete statistics possible.

STATISTICS OF COLLEGES

On pages 546 to 549 is Table 1, which gives all the colleges in session during 1908-9, the population of the city in which each college is located, the number of students, men and women, registered during the year, the number of 1909 graduates, men and women, the number of graduates holding collegiate degrees, the number of teachers for each college, the number of weeks of actual work in the college year, the total fees for each year, the executive officer of the college and the dates of beginning and ending of the next session. The figures in heavy-faced type show the totals by states. Beginning on page 531 are given essential facts of all medical colleges, arranged by states, and on pages 549 to 555 the requirements and membership of the different college associations.

NUMBER OF MEDICAL STUDENTS

The total number of medical students (matriculants) in the United States for the year ending June 30, 1909, excluding special students, was 22,145, a decrease of 457 below 1908 and a decrease of 2,131 below 1907. It is the lowest number since THE JOURNAL began compiling these statistics in 1900. Of the total number of students, 20,554 were in attendance at the regular colleges, 899 at the homeopathic, 413 at the eclectic, 52 at the physiomedical, and 227 at the unclassifiable colleges. The attendance at the regular colleges shows a decrease of 382 below that of last year, of 1,649 below 1907 and of 2,562 below 1906. In the homeopathic colleges there was an increase of 9 over the attendance of 1908, but a decrease of 140 below the attendance of 1907. The eclectic colleges show a decrease of 66 since 1908, of 132 below 1907 and of 231 below 1906. The physiomedical colleges had 52 this year, as compared with 90 in 1908 and 97 in 1907.

TABLE 4.—MEDICAL COLLEGE ATTENDANCE

Year.	Regular.	Homeopathic.	Eclectic.	Physio Med..	Nondescript.	Total.
1880	9,776	1,220	830	....	....	11.826
1890	13,521	1,164	719	....	....	15,404
1900	22,710	1,909	522	....	....	25,171
1901	23,846	1,683	664	80	144	26.417
1902	24,878	1,617	765	91	150	27,501
1903	24,930	1,498	848	149	190	27,615
1904	24,662	1,309	1,014	123	234	28,142
1905	24,119	1,104	578	114	232	26,147
1906	23,116	1,085	644	110	249	25,204
1907	22,303	1,039	545	97	292	24,276
1908	20,936	891	479	90	206	22,602
1909	20,554	899	413	52	227	22,145

GRADUATES

The total number of graduates for the year ending June 30, 1909, was 4,442, a decrease of 299 below 1908, a decrease of 538 below 1907, and of 922 below 1906. The percentage of graduates to matriculants was 20.1, as compared with 21.0 in 1908 and 20.5 in 1907. The number of graduates from the regular colleges was 4,090, or 280 less than in 1908 and 501 less than in 1907. From the homeopathic colleges there were 209 graduates, or 6 less than in 1908 and 16 less than in 1907. The eclectic colleges graduated 84, or 32 less than last year and 37 less than in 1907. The physiomedical colleges had 15 graduates this year, as compared with 12 last year and 11 in 1907.

TABLE 5.—MEDICAL COLLEGE GRADUATES

Year.	Regular.	Homeopathic.	Eclectic.	Physio-Med.	Nondescript.	Total.
1880	2,673	380	188	....	....	3,241
1890	3,853	380	221	....	....	4,454
1900	4,715	413	86	....	....	5,214
1901	4,879	387	148	18	12	5.444
1902	4,498	336	138	16	11	4,999
1903	5,088	420	149	24	17	5,698
1904	5,190	371	146	20	20	5,747
1905	5,126	276	153	22	23	5,600
1906	4,841	286	186	22	29	5,364
1907	4,591	225	121	11	32	4,980
1908	4,370	215	116	12	28	4,741
1909	4,090	209	84	15	44	4,442

Of the 4,442 medical graduates, 692, or 15.6 per cent., were reported to hold also degrees in arts or science, as compared with 820 (17.3 per cent.) in 1908, and 903 (18 per cent.) in 1907. It is expected that in future the percentage of college graduates will increase rather than decrease, since more medical schools are requiring some college work for admission.

WOMEN IN MEDICINE

During the past year there were 921 women studying medicine, an increase of 86 over 1908, but 7 less than in 1907. The percentage of all medical students was 4.2, as compared with 3.7 per cent. last year. There were 162 women graduates this year, or 3.7 per cent. of all graduates. In 1908 there were 835 women students and 185 graduates, while in 1907 there were 928 women students and 211 graduates. Of all the women matriculants, 169 (18.4 per cent.) were in attendance at the 3 medical colleges for women, as compared with 186 (22.3 per cent.) in 1908 and 210 (22.6 per cent.) in 1907. From the 3 women's colleges, there were 33, or 20.3 per cent., of all women graduates, as compared with 46 (24.9 per cent.) in 1908. The remaining 752 (81.6 per cent.) were matriculated in coeducational colleges.

NUMBER OF COLLEGES

During the past year 11 colleges (mentioned on page 555) have either suspended or have merged into others and 3 new colleges were established, making a net decrease of 8 colleges since last year, the total now being 144. The regular colleges number 117, a decrease of 6 since last year. The homeopathic colleges number 14, a decrease of 2. Of the eclectic colleges, during the year, one changed to regular, but one new college was organized, leaving 8, the same number as last year. There are still 2 physiomedical colleges and 3 schools which are unclassifiable since they offer to teach two or more systems of medicine.

TABLE 7.—Medical Colleges

Year.	Regular.	Homeopathic.	Eclectic.	Physio-Med.	Nondescript.	Total.
1880	72	12	6	....	....	90
1890	93	14	9	....	....	116
1900	121	22	8	....	....	151
1901	124	21	10	2	2	159
1902	121	20	10	3	1	155
1903	121	19	10	3	1	154
1904	133	19	10	3	1	166
1905	129	18	9	3	1	160
1906	130	18	9	3	1	161
1907	131	17	8	3	2	161
1908	123	16	8	2	3	152
1909	117	14	8	2	3	144

The total number of colleges which have ceased to exist through mergers or otherwise since 1904 is 45. During the same time, however, 23 new colleges have been organized, leaving a net decrease of 22. While the total number of colleges is smaller, the percentage of higher-grade, stronger medical colleges has been considerably increased.

LENGTH OF TERMS

The length of term of each college fluctuates somewhat from year to year, but on the whole during the last six years there has been a decided lengthening of college terms. This has reference to the weeks of actual work, exclusive of holidays. Four colleges this year report sessions shorter than twenty-seven weeks, as compared with 2 last year and 6 in 1907. In 1901 there were 58 which held sessions of less than twenty-seven weeks. Of those having sessions of twenty-seven or twenty-eight weeks, the number is 17 this year, or 4 less than last year and 29 less than in 1903. There are 23 colleges claiming courses of twenty-nine or thirty weeks of actual work and 51 claiming courses of thirty-one or thirty-two weeks. The 3 colleges claiming courses longer than thirty-six weeks are night schools. It would doubtless require twelve or fourteen years of the usual night-school study, however, to secure the equivalent of four years of thirty weeks each in the better day colleges. Ninety-nine, or 68 per cent. of all colleges, require from thirty-one to thirty-six weeks, as compared with 64 per cent. last year.

TABLE 8.—College Terms

Year.	23 to 26 weeks.		27 to 28 weeks.		29 to 30 weeks		31 to 32 weeks.		33 to 34 weeks.		35 to 36 weeks.		Ov. 36 weeks

TUITION AND OTHER FEES

Special attention is called this year in Table 1 to the total amount charged by the various colleges for tuition, matriculation, laboratory and graduation fees *per annum* for each student. For the 139 colleges from which complete information was received regarding fees, various amounts are changed as follows:

Total Fees.	Colleges.
$ 50 or less..............................	7
50 to $ 75..............................	11
75 to 100..............................	37
100 to 125..............................	36
125 to 150..............................	19
150 to 175..............................	17
175 to 200..............................	7
200 or above..............................	5

Only 18 charge fees less than $75 *per annum*, among these appearing the state universities of Colorado, Iowa, Missouri, North and South Dakota, Oklahoma and Wisconsin, where there is charge only for matriculation and laboratory fees, no tuition being required. The others are schools for colored students. The highest number, 37, is of the colleges charging from $75 to $100, and there are 36 which charge from $100 to $125, making 73 colleges charging fees ranging from $75 to $125 per year. There are 36 colleges having fees of $125 to $175 per year and 12 having fees of $175 or above. The 5 colleges having the highest fees are Johns Hopkins University Medical Department, Harvard Medical School, University and Bellevue Hospital Medical College, Columbia University College of Physicians and Surgeons and the Medical Department of the University of Pennsylvania. The highest fees, ranging from $250 to $275, are charged by Columbia University College of Physicians and Surgeons.

From a knowledge based on an actual inspection of all medical schools, it can be stated that among those colleges charging low fees are to be found a fair number of medical colleges of high grade, while, on the other hand, some colleges of low rank charge high fees. From the monetary standpoint, therefore, there is no reason why a student of limited means should attend a low-grade medical college. The figures here given are particularly interesting in the light of the facts already made known[1] that, in the twenty-five leading medical colleges, to teach each student in the freshman and sophomore years costs the colleges from $250 to $700 or even more each year.

DISTRIBUTION OF MEDICAL STUDENTS

Table 2 on pages 550 to 554 shows from what states the students come who were in attendance at each medical college during the session of 1908-9. The influence of the proximity of the medical school is seen in the fact that states having medical colleges contribute more students in proportion to the population than those which have no colleges. A comparison of this table with the large tables based on state board examinations[2] which show the distribution of the alumni of each college, is interesting. The college whose alumni are widely distributed usually has a student body from an equally large number of states.

Only two states contributed over 2,000 students each this year, these being Pennsylvania with 2,159 and New York with 2,123. Illinois contributed 1,920. The next states in the order of the number of students contributed are Ohio, 929; Massachusetts and Missouri, each, 813; Texas, 751, and Iowa, 722. Four states have less than 20 each, these being Wyoming, 14; Arizona, 12; Nevada, 8, and New Mexico, 8. There were 83 students from Hawaii, Porto Rico and the Philippine Islands and 539 students from foreign countries.

MIGRATION OF MEDICAL STUDENTS

Table 3 has been prepared to show the number of students of each section of the country which attend medical schools of that section and the number which attend medical colleges of other sections. Section A gives the figures for students from the eastern states; Section B, for students from the middle states; Section C, for students from the western states, and Section D, for students from the southern states. Figures are given for the two college years, 1907-8 and 1908-9. The differences in the figures for the two years show the fluctuation due to the exit of the graduating class, to the ingress of the new freshmen and to the comparatively few which during the year left the colleges of one section and went to colleges of another section. At the bottom of Section D the average totals for the two years are given. Percentages are given in order to permit of comparisons. The eastern section has long held the largest place in medical education and, as would be expected, still has the smallest percentage of students leaving to attend colleges of other sections, the percentage of those remaining in the eastern section being 92.1. The middle states are a close second, with 91.7 per cent. of their own resident students studying medicine in that section. The western section, having the smallest number of colleges, naturally has a larger proportion of students attending colleges in other sections. Of the students who migrate from the middle and southern sections, the largest proportions go east, while of those from the western section the largest proportion attends colleges of the middle section. Altogether 2,490 students attended colleges outside of the section in which they lived. Of this number, 1,019, or 40.9 per cent., went to the eastern section; 1,016, or 40.8 per cent., went to the middle section; 321, or 12.5 per cent., went to the southern section, and 134, or 5.4 per cent., went to the western section.

PRESENT STATUS IN MEDICAL EDUCATION

Attention should be drawn to the demoralizing influence of medical sects, particularly osteopathy, which have secured special legislation in a number of states. This is more fully discussed in another column.[3] A careful study of the entire field of medical education, however, shows that marked progress has been made, due chiefly to the action of the medical faculties themselves, which, recognizing the need of higher and better enforced standards, have made great sacrifices and gone to much expense to bring about the desired end. As is noted in another column,[4] there are 24 colleges which after this fall will be requiring one or more years of collegiate work for admission. Numerous mergers have been brought about, better equipped laboratories have been provided, better trained teachers have been employed and increased endowments secured. There is, indeed, a bright outlook for the future of medical education.

THE SCIENCE OF CLINICAL MEDICINE

The development of medicine during the past twenty-five years has resulted in the separation of anatomy, pathologic anatomy, physiology, physiologic chemistry and pharmacology as distinct branches of medicine, which formerly constituted a unit. Each of these subjects is now generally recognized as a pure science and has its quota of able men devoting their best energies to the further advancement of that science.

In this issue of The Journal, Dr. S. J. Meltzer calls attention to the growing demand for the separation of another branch from the mother-stem—the division of the science of clinical medicine from the practice of medicine. Such separation seems necessary, since the two divisions of medicine are necessarily incompatible. Clinical research desires to delve into the unknown to seek for new truths, while practice cares chiefly for things of already proved value in diagnosis or treatment. As Dr. Meltzer points out, for the scientific side of clinical medicine utility only obscures vision and retards progress, while in the practice of medicine utility is of chief consideration. Furthermore, the research side needs scientific men whose time is devoted to the following up of details now seemingly unimportant, and sufficient time is not available for those engaged in active practice.

[2] The Journal, May 22, 1909, pages 1698 to 1713.
[3] This issue, page 582.
[4] This issue, page 555.

The responsibility for this work cannot well be left with the anatomist, the physiologist or the pathologist, who with few exceptions have little conception of the clinical problem, for as a rule they are not clinically trained. The longer they work at their special branches and the older they become, the wider as a rule becomes the gap between the hospital wards and their laboratories. The development of the scientific side of clinical medicine, therefore, would tend to lessen the breach between the so-called scientific and so-called practical sides of medicine, and, as Dr. Christian points out,[1] will insure that "the physician of the future is both scientifically and practically trained in laboratory methods, but none the less a keen observer of his patients and so an able clinician in the truest sense."

The proposed separation would be clearly beneficial for both divisions of medicine. The development of the scientific side of clinical medicine would attract men of marked ability whose work would doubtless soon bring out new methods of diagnosis and treatment, thereby adding to the resources of the practitioner. While much has already been done through research in physiology, physiologic chemistry and pharmacology, how much more can be done if able men, trained in scientific methods, devote their lives to the further development of clinical methods! If it is to hold its place in the present rapid progress being made in the sciences of medicine, it is apparent that the scientific side of clinical medicine should be separated from active practice.

THE INFLUENCE OF THE CARNEGIE FOUNDATION ON MEDICAL EDUCATION

Science and higher education in this country have been placed under lasting obligation to Mr. Andrew Carnegie by his endowment of the two great institutions that bear his name—the Carnegie Institution of Washington and the Carnegie Foundation for the Advancement of Teaching. The first is devoted wholly, or practically so, to active investigation in other fields than the purely medical, the founder and his advisers believing that the needs of medical investigation would be well cared for in other ways. The Carnegie Institution, however, supports the *Index Medicus* and thus renders a most important and direct service to medicine of greater influence than is perhaps sufficiently appreciated by many in and out of the medical profession. If that unique publication, which is the only index of the current medical literature of the world that we have, were allowed to go under it would be a most lamentable loss to medicine. The number of periodicals now is so large that without such index it would be utterly impossible for our writers and investigators to keep adequately in touch with the additions constantly made to medical knowledge in all civilized countries. It is hoped that the trustees of the Carnegie Institution may have become so impressed with the great usefulness of the *Index Medicus* in promoting the growth of medical knowledge that no doubt will arise as to the wisdom of its continuance.

The Carnegie Foundation for the Advancement of Teaching, the influence of which on medical education it seems desirable to emphasize at this time, was established in order to provide retiring allowances and pensions for teachers in colleges and universities in this country and Canada. Of course, this does not mean every institution that calls itself college or university. In addition to fulfilling certain more or less obvious requirements, an institution in order to be acceptable must be non-sectarian. At first state universities also were excluded, but a little more than a year ago the endowment was increased by $5,000,000 in order that the benefits of the fund might be extended to state universities. A large proportion of the universities that participate in this pension system maintain medical departments, and members of their medical faculties that follow medical teaching as a career are as fully entitled, and as freely admitted, to pensions as members of other faculties. Already not a few medical teachers have retired on Carnegie allowances. The Carnegie Foundation consequently stands for the advancement of medical teaching to quite the same degree as it stands for the advancement of teaching in other branches.

This provision for pensions for medical teachers will help medical education because the career as medical teacher thereby naturally becomes more attractive to the right sort of men. Relieved in a measure from financial responsibility in case of disability from sickness and old age, the medical scholar will feel himself freer to devote himself unreservedly to his teaching and investigation than otherwise would be the case. As yet only a relatively small part of the total number of our medical schools derive direct benefit from this pension fund, and this number unfortunately can not be expected to be increased speedily by reason of the self-evident limitations of so many of our schools, every one of which we all know should be acceptable to the foundation so far as the character of the work done is concerned. Our efforts to raise the standards must not cease until such is the case.

But the Carnegie Foundation is a factor of great importance to medical education for other reasons, as well. It is evident that the work of the institutions that are admitted to the benefits of a pension system of this kind must be kept up to a reasonable standard. The officers and experts of the foundation must assure themselves that such is the case. By virtue of this fact the foundation not only feels, as it were, a special and direct interest in the work of a number of our medical schools, but must concern itself with the broad subject of medical education in general. as well. We have abundant evidence that this interest is actual.

---

[1] Columbia University Quarterly, June, 1909, page 341.

According to current reports, the medical work is investigated with the same thoroughness as other phases of the institutions in which the foundation has become interested, and as a result undesirable conditions and shortcomings have been brought to light which call for change and improvement. Noteworthy forward steps, especially in the line of consolidation of medical schools, have received effective encouragement from the Carnegie Foundation. From time to time we may expect that the foundation will find it expedient also to carry out comprehensive investigations of all the medical schools in the country so as to be able better to judge of the trend of development. If the results of expert work along these lines were given full publicity much good would surely come of it to medical education in general. The actual facts would be more helpful in the end than the poetry of the medical school catalogues and advertisements, especially to state licensing boards, some of which maintain altogether too much indifference in regard to the character of the schools that send them applicants for license. It is evident that on account of its unique relation the Carnegie Foundation, wisely managed, may exert a powerful and growing influence for good on the development of medical education in this country.

OUR COLLEGES AND THE TUBERCULOSIS CAMPAIGN

An unusually interesting and important phase of the tuberculosis campaign, dealing with the work carried on at our colleges and universities against this disease, is presented in a paper by W. H. Norton[1] read before the recent International Congress of Tuberculosis at Washington, D. C. Since the tuberculosis question has resolved itself largely into one of education of the masses our educational institutions necessarily will occupy an important place in its solution. For them to carry on or aid in this fight they need first-hand instruction in questions concerning especially hygiene and sanitation. In many of our higher institutions, courses are now being given in the class-room by competent and trained specialists, amplified by work of a more practical character, such as excursions to large cities to study the social and economic aspects of the question.

At the University of Wisconsin, for instance, classes in the departments of sociology and economics visit Milwaukee to study the disease from their respective viewpoints, and in many colleges investigative work with reference to such problems as the proportion of deaths from tuberculosis, economic losses, recurrence of the disease in infected houses, local conditions and surroundings, etc., is carried on with satisfactory results. Of the higher institutions of learning about one-fifth are engaged in such work of investigation. In addition to this at least 15 colleges and universities in this country offer extension lectures on tuberculosis, and in Wisconsin special lectures on this subject have been given for some years at farmers' institutes and before teachers' meetings in the state.

Another phase of the question concerns the study of tuberculosis among students and the transmission of the disease in the class-room and rooming houses. In some colleges practical illustrations of disinfection of rooms are given and immediate attention is paid to incipient cases of tuberculosis. Rules have been passed, in some instances, which prohibit students living in houses inhabited by tuberculous families, and committees on hygiene are active in obtaining information which can be used for the protection of students and in controlling the disease.

The influence of an army of young minds interested in this question, leaving our higher institutions and destined to become leaders in all phases of life, must sooner or later be of the greatest moment. Such persons, becoming business men and employers, will surely give more attention to the laws of hygiene and sanitation in work shops, factories, business houses, etc. Or, becoming our legislators, they will respect attempts of the medical profession to place on our statute books laws protecting the health of the people, preventing contagion and establishing state sanatoria, hospitals, etc. Or, becoming teachers in our public or private schools, they will influence the hundreds of thousands of boys and girls in a manner which can only be for the enlightenment of the masses of people regarding questions of hygiene.

While much has already been done along the lines indicated above, still more than one-half of the educational institutions of the country have not yet interested themselves in this problem. There is, therefore, much room for improvement, and undoubtedly, as Norton states, those who have not yet become actively engaged in this work are alive to its importance and soon will cooperate and lend a hand.

THE CROWDED MEDICAL CURRICULUM

During the past year one of the most important subjects of discussion has been the crowded medical curriculum. There are so many subjects in the curriculum of medical schools that it is difficult for students to get clear ideas with regard to them. This overcrowding is becoming worse every year in spite of all that has been done. At first, the overcrowding was only in the final years of the medical course and temporary improvement was effected by transferring several subjects to earlier years; but now the overcrowding, involving all years, is worse than ever. Some colleges, by increasing the entrance requirements to one or more years of collegiate work, including physics, inorganic chemistry and biology, thereby relieved the medical curriculum of those branches and secured for the medical course students better prepared to take up the medical subjects. In the Canadian schools, instead of requiring collegiate work for admission, the medical course was extended to five years, the first of which was devoted to physics, chemistry and biology. But, even relieving the medical course of these premedical sciences gives only slight relief, and teachers are justly clamoring for more time. Medical students are being ground through a cramming process with insufficient time to think. An extension of the medical course to five years has been suggested, and this may become necessary before many years. As will be noted in a chart on page 542 showing the length of medical courses at home and abroad, in European countries, Austria, Belgium and Portugal have a five-year course and also require a year of science beyond the secondary school for admission, which is practically the equivalent to the requirements in Denmark, Italy, the Netherlands and Norway, as well as in the South American countries—Argentina, Brazil and Uruguay—where a six-year course, including the premedical sciences, is required. Spain has a seven-year course if we include the year in science, while Sweden has a course of eight or ten years, depending on the student's ability to pass his examination. We are not quite ready, however, for this extension of the medical course. In the meantime it should be the purpose of those interested in medical education to secure, so far as possible, the obliteration of the feeling of hurry and the sense of overcrowding in present-day medical study, both of which are fatal to any real attainment of knowledge.

---

[1] Science, 1909, xxx, 6.

The old Greek term which is the root of our word school meant leisure. The Latin expression *vacare rei* meant to be free for a thing and therefore to apply one's self assiduously to a subject. It is only when the mind feels itself free to apply itself that there is real attainment. All agree that at present this state of mind is practically impossible in medical schools. A constant rush and hurry stimulates to cramming and memory work but does not conduce to real education: that is, to the bringing out of mental powers in such a way as to develop the students' mental faculties. The purpose of education is to make men think, supplying them with sufficient facts to illustrate the important principles and trusting to them to accumulate whatever other facts they need to apply those principles.

It is the giving of information that is occupying so much attention in our medical schools as to overcrowd the curriculum. The requirements of medical education are such that a man must take about six hours of class-room work of one kind or another every day for six days in the week. In medical schools, therefore, thirty-five hours a week are almost obligatory, which is much more time than is required in other departments of universities where courses requiring twenty hours of work a week are considered quite enough. It is a well-recognized principle in pedagogics that if a student is to derive the proper amount of benefit from class-room work he must occupy about as much time in private study as he spends in the class room. It is absurd, therefore, to think of medical students spending six hours in study besides their six hours of class-room work. An eight-hour day in the intellectual world is even more important than for the manual workman. A man may do ten hours of work with his mind but it is never well done and some of it were better not done.

Over and over again in recent years attention has been called to the fact that it is the medical school that sets the worst possible example with regard to the hygiene of education. The average medical student loses more weight and takes his final examinations much more to heart than do students in any other department. We should of course be setting an example in this matter in quite another way. There are many who will say that it is only by long hours of classwork that the medical student can be made to learn all that he has to know for examinations. This is unfortunate if true, for on his capacity to study after he has graduated depends his future career. Commencement is literally the beginning of medical education for a physician. It is what he will learn in the next ten years that counts. How well has he been taught to study for himself, to observe for himself, to think for himself? This ability means most for his future. Is it not possible that we are trying to convey too much information and not furnishing real education; that we are not developing the intellectual powers of the student? It would be worth while to have the problem placed squarely before us at the beginning of the new year.

PRESERVATION OF MEDICAL HISTORICAL RECORDS

An immediate lively awakening of interest in the preservation of the records of American medical history is needed if important material is not to be lost forever within the next decade. The men who knew well the second generation of important contributors to medicine in the United States—"and there were giants in those days"—are now passing away, and with them is likely to pass not only the knowledge, but also the documentary evidence for much of the medical history of the early part of the latter half of the nineteenth century. So long as they were alive their affection for their old masters kept together precious material. This now is likely to be lost from sight unless care is exercised during the next few years.

Such an event is, of course, not likely in the larger cities and for the eastern part of the country perhaps. It must not be forgotten that the West and the South, however, contributed very materially to the progress of medical science during the centuries just passed. The selves that such is the case. By virtue of this fact the foundation not only feels, as it were, a special and direct interest in the work of a number of our medical schools, but must concern itself with the broad subject of medical education in general, as well. We have abundant evidence that this interest is actual.

According to current reports, the medical work is investigated with the same thoroughness as other phases of the institutions in which the foundation has become interested, and as a result undesirable conditions and shortcomings have been brought to light which call for change and improvement. Noteworthy forward steps, especially in the line of consolidation of medical schools, have received effective encouragement from the Carnegie Foundation. From time to time we may expect that the foundation will find it expedient also to carry out comprehensive investigations of all the medical schools in the country so as to be able better to judge of the trend of development. If the results of expert work along these lines were given full publicity much good would surely come of it to medical education in general. The actual facts would be more helpful in the end than the poetry of the medical school catalogues and advertisements, especially to state licensing boards, some of which maintain altogether too much indifference in regard to the character of the schools that send them applicants for license. It is evident that on account of its unique relation the Carnegie Foundation, wisely managed, may exert a powerful and growing influence for good on the development of medical education in this country.

OUR COLLEGES AND THE TUBERCULOSIS CAMPAIGN

An unusually interesting and important phase of the tuberculosis campaign, dealing with the work carried on at our colleges and universities against this disease, is presented in a paper by W. H. Norton[1] read before the recent International Congress of Tuberculosis at Washington, D. C. Since the tuberculosis question has resolved itself largely into one of education of the masses our educational institutions necessarily will occupy an important place in its solution. For them to carry on or aid in this fight they need first-hand instruction in questions concerning especially hygiene and sanitation. In many of our higher institutions, courses are now being given in the class-room by competent and trained specialists, amplified by work of a more practical character, such as excursions to large cities to study the social and economic aspects of the question.

At the University of Wisconsin, for instance, classes in the departments of sociology and economics visit Milwaukee to study the disease from their respective viewpoints, and in many colleges investigative work with reference to such problems as the proportion of deaths from tuberculosis, economic losses, recurrence of the disease in infected houses, local conditions and surroundings, etc., is carried on with satisfactory results. Of the higher institutions of learning about one-fifth are engaged in such work of investigation. In addition to this at least 15 colleges and universities in this country offer extension lectures on tuberculosis, and in Wisconsin special lectures on this subject have been given for some years at farmers' institutes and before teachers' meetings in the state.

Another phase of the question concerns the study of tuberculosis among students and the transmission of the disease in the class-room and rooming houses. In some colleges practical illustrations of disinfection of rooms are given and immediate attention is paid to incipient cases of tuberculosis. Rules have been passed, in some instances, which prohibit students living in houses inhabited by tuberculous families, and committees on hygiene are active in obtaining information which can be used for the protection of students and in controlling the disease.

The influence of an army of young minds interested in this question, leaving our higher institutions and destined to become leaders in all phases of life, must sooner or later be of the greatest moment. Such persons, becoming business men and employers, will surely give more attention to the laws of hygiene and sanitation in work shops, factories, business houses, etc. Or, becoming our legislators, they will respect attempts of the medical profession to place on our statute books laws protecting the health of the people, preventing contagion and establishing state sanatoria, hospitals, etc. Or, becoming teachers in our public or private schools, they will influence the hundreds of thousands of boys and girls in a manner which can only be for the enlightenment of the masses of people regarding questions of hygiene.

While much has already been done along the lines indicated above, still more than one-half of the educational institutions of the country have not yet interested themselves in this problem. There is, therefore, much room for improvement, and undoubtedly, as Norton states, those who have not yet become actively engaged in this work are alive to its importance and soon will cooperate and lend a hand.

THE CROWDED MEDICAL CURRICULUM

During the past year one of the most important subjects of discussion has been the crowded medical curriculum. There are so many subjects in the curriculum of medical schools that it is difficult for students to get clear ideas with regard to them. This overcrowding is becoming worse every year in spite of all that has been done. At first, the overcrowding was only in the final years of the medical course and temporary improvement was effected by transferring several subjects to earlier years; but now the overcrowding, involving all years, is worse than ever. Some colleges, by increasing the entrance requirements to one or more years of collegiate work, including physics, inorganic chemistry and biology, thereby relieved the medical curriculum of those branches and secured for the medical course students better prepared to take up the medical subjects. In the Canadian schools, instead of requiring collegiate work for admission, the medical course was extended to five years, the first of which was devoted to physics, chemistry and biology. But, even relieving the medical course of these premedical sciences gives only slight relief, and teachers are justly clamoring for more time. Medical students are being ground through a cramming process with insufficient time to think. An extension of the medical course to five years has been suggested, and this may become necessary before many years. As will be noted in a chart on page 542 showing the length of medical courses at home and abroad, in European countries, Austria, Belgium and Portugal have a five-year course and also require a year of science beyond the secondary school for admission, which is practically the equivalent to the requirements in Denmark, Italy, the Netherlands and Norway, as well as in the South American countries—Argentina, Brazil and Uruguay—where a six-year course, including the premedical sciences, is required. Spain has a seven-year course if we include the year in science, while Sweden has a course of eight or ten years, depending on the student's ability to pass his examination. We are not quite ready, however, for this extension of the medical course. In the meantime it should be the purpose of those interested in medical education to secure, so far as possible, the obliteration of the feeling of hurry and the sense of overcrowding in present-day medical study, both of which are fatal to any real attainment of knowledge.

---

[1] Science, 1909, xxx, 6.

The old Greek term which is the root of our word school meant leisure. The Latin expression *vacare rei* meant to be free for a thing and therefore to apply one's self assiduously to a subject. It is only when the mind feels itself free to apply itself that there is real attainment. All agree that at present this state of mind is practically impossible in medical schools. A constant rush and hurry stimulates to cramming and memory work but does not conduce to real education: that is, to the bringing out of mental powers in such a way as to develop the students' mental faculties. The purpose of education is to make men think, supplying them with sufficient facts to illustrate the important principles and trusting to them to accumulate whatever other facts they need to apply those principles.

It is the giving of information that is occupying so much attention in our medical schools as to overcrowd the curriculum. The requirements of medical education are such that a man must take about six hours of class-room work of one kind or another every day for six days in the week. In medical schools, therefore, thirty-five hours a week are almost obligatory, which is much more time than is required in other departments of universities where courses requiring twenty hours of work a week are considered quite enough. It is a well-recognized principle in pedagogics that if a student is to derive the proper amount of benefit from class-room work he must occupy about as much time in private study as he spends in the class room. It is absurd, therefore, to think of medical students spending six hours in study besides their six hours of class-room work. An eight-hour day in the intellectual world is even more important than for the manual workman. A man may do ten hours of work with his mind but it is never well done and some of it were better not done.

Over and over again in recent years attention has been called to the fact that it is the medical school that sets the worst possible example with regard to the hygiene of education. The average medical student loses more weight and takes his final examinations much more to heart than do students in any other department. We should of course be setting an example in this matter in quite another way. There are many who will say that it is only by long hours of classwork that the medical student can be made to learn all that he has to know for examinations. This is unfortunate if true, for on his capacity to study after he has graduated depends his future career. Commencement is literally the beginning of medical education for a physician. It is what he will learn in the next ten years that counts. How well has he been taught to study for himself, to observe for himself, to think for himself? This ability means most for his future. Is it not possible that we are trying to convey too much information and not furnishing real education; that we are not developing the intellectual powers of the student? It would be worth while to have the problem placed squarely before us at the beginning of the new year.

PRESERVATION OF MEDICAL HISTORICAL RECORDS

An immediate lively awakening of interest in the preservation of the records of American medical history is needed if important material is not to be lost forever within the next decade. The men who knew well the second generation of important contributors to medicine in the United States—"and there were giants in those days"—are now passing away, and with them is likely to pass not only the knowledge, but also the documentary evidence for much of the medical history of the early part of the latter half of the nineteenth century. So long as they were alive their affection for their old masters kept together precious material. This now is likely to be lost from sight unless care is exercised during the next few years.

Such an event is, of course, not likely in the larger cities and for the eastern part of the country perhaps. It must not be forgotten that the West and the South, however, contributed very materially to the progress of medical science during the centuries just passed. The

South was, indeed, much more important than any other part of the country for the originality of its medical science, and we owe to it anesthesia, the first gynecologic operations, the manufacture of artificial ice and other important inventions and discoveries. In the early part of the nineteenth century we had more fellows of the Royal Society in this country than we have at the present time, and most of them were from the South. They were men who had made brilliant studies in Europe and who then settled down into what might seem to us a narrow environment and did fine original work of high character, though we are only just beginning to appreciate all the significance of it. As to how much was accomplished in the West, Dr. Juettner's book[1] on "Daniel Drake and His Followers" furnishes abundant evidence and at the same time makes very clear how interesting is the story of American medicine when properly told.

It is perfectly possible for us to miss important records for the history of medicine if we neglect the compilation of documents at the present time. We called attention editorially in The Journal some time ago[2] to the fact that even for so important a phase of medical and surgical history as anesthesia we can learn some facts from non-medical writers that are unobtainable from those who wrote deliberately about medicine. We have been accustomed to think that surgical anesthesia was a new thing in the world, though many of the well-known poets and literary men during the three centuries after the fourteenth draw figures from "the mercies of old surgeons who put their patients to sleep before they cut them." Even for so important a disease as tuberculosis the informal gleanings of medical history to be found in non-medical writers are almost more informing and are more interesting than medical history; the same thing is true regarding leprosy.

We welcome, then, the formation of the "Western Association for the Preservation of Medical Records" which has recently been organized[3] in the middle West. The fact that prominent members of the profession who practice medicine in various phases besides the regular school are connected with it as vice-presidents will surely bring about the preservation of the records of sectarian medicine—a consummation eminently to be wished—for this will be extremely interesting after another generation, when medical differences shall have passed away. It must not be forgotten that every phase of medical history will be of interest. Librarians used to bind magazines without their advertising pages. Now we know that the advertising pages of a magazine of any kind often contain more valuable historical matter than the body of the magazine. Precious documents relating to the practice of medicine in our time are to be found even in the flying leaflets issued for advertising purposes. We know a man who, with the historical instinct, faithfully preserved every document of any kind relating to medicine that came to him in the course of twenty years. No matter how trivial it might seem, it was put away in a large room with the others. When at the end of the time he presented his collection to the College of Physicians in Philadelphia it was unique of its kind and contained material of the greatest value for the future historian of medicine in America.

We commend heartily the effort to seek out and preserve all documents that may have a bearing on medical history. We now have enough medical libraries in this country whose controlling boards are quite willing, even anxious, to guarantee the preservation of such material, therefore there need be no excuses on account of the bother or the space required for such things or any reasonable objection to their preservation. Let us hope that similar associations like that we have mentioned will be formed and that everywhere throughout the country some men at least will take on themselves the duty, for it is a precious duty to the American profession of the future, of encouraging an interest in medical history and doing everything they can to preserve the records of it.

Medical News

ALABAMA

Medical College Increases Capital Stock.—Notice has been filed with the secretary of state that the capital stock of the Birmingham Medical College has been increased from $15,000 to $75,000.

First-Aid Corps to Be Organized.—The Tennessee Company has decided to organize a first-aid corps at six of its mining camps, and if the experiment succeeds, a detachment will be maintained at each of the mining camps of the company. The work is in charge of Dr. Matthew J. Shields.

Antituberculosis League Meeting.—At the annual election of officers of the Montgomery Antituberculosis League, Dr. Frank H. McConnico was elected a vice-president, Dr. Gaston J. Greil, chairman of the executive committee, and Drs. Forney C. Stevenson and Glenn Andrews members of the committee. During the past year the league has established two dispensaries and distributed about 25,000 leaflets and 8,000 booklets setting forth the local health conditions. During the year, 30 cases of tuberculosis were cared for by the league, only 6 of which were in white people.

Personal.—Dr. Frank P. Petty, New Decatur, has been elected health officer of Morgan County, vice Dr. Scott L. Rountree, deceased.——Dr. Miles P. Hughes, Gadsden, has been appointed a member of the board of pension examining surgeons for Etowah county, vice Dr. John C. Slack, resigned.——Dr. Peter Binford, Somerville, suffered a second cerebral hemorrhage recently and is said to be in a precarious condition.——Dr. William D. Fonville, Ensley, has been elected health officer of Birmingham.——Dr. William G. Somerville and family, Tuscaloosa, have sailed for Europe.

ARKANSAS

Sanitarium Incorporates.—Park Springs Sanitarium has been incorporated at Bentonville with a capital stock of $50,000.

Eclectic Medical Board Election.—The Arkansas State Eclectic Medical Board elected the following officers July 14: president, Dr. Claud E. Laws, Fort Smith; secretary, Dr. Andrew J. Widener, Little Rock; and treasurer, Dr. Pearl H. Tatman, Eureka Springs.

CALIFORNIA

Medical Society Incorporates.—The San Joaquin Medical Society has filed a petition for incorporation. The object of the action is declared to be the prevention of illegal, improper and unlicensed medical practice.

Must Not Distribute Questionable Medical Advertisements.—The police committee of the board of supervisors of San Francisco county have approved an ordinance prohibiting the distribution of advertisements of medical concerns of questionable standing.

Camp of Instruction at the Presidio.—A military camp of instruction for medical officers of the militia opened at Presidio July 15, with Major Albert E. Truby, medical corps, U. S. A., in command. Each state of the Pacific Coast has sent representatives from the medical department of its national guard, in all 25, to take the course.

Tuberculosis in California.—Tuberculosis is a cause of more deaths in cities than in the rural districts in California. Of the deaths recorded 15 per cent. of those in cities in 1908 were from tuberculosis, while 14.1 per cent. of all deaths were from this cause in the remainder of the state. Eight cities show a percentage above the average of 15 and 11 cities have a lower average.

New Hospitals.—The plans for St. Francis Hospital, San Francisco, have been completed, and estimates are now being taken. The building will probably cost about $200,000. Dr. John Gallwey is president, Dr. Walter B. Coffey vice-president, and Dr. John O'Connor secretary of the institution.——A new clinical building is being erected as rapidly as possible by the San Francisco Association for the Study and Prevention of Tuberculosis. It is expected it will be ready to open October 1.——The Southern Pacific Railway Company formally opened its hospital at Baker and Fell streets, San Francisco, July 15. The building and its equipment have cost nearly a million dollars.——The first hydrotherapeutic institution to establish in the west will soon be opened at the Stockton State Hospital.

Personal.—Dr. Weston O. Smith, Alameda, was thrown from a mule on a trail in the Yosemite Valley recently, breaking his left arm near the wrist.——Dr. William H. Davies, Monterey, has lost the sight of his right eye from cataract.——Dr. Mark F. Hopkins has been appointed member of the San Jose Board of Health.——Dr. Rudolph W. Baum has been elected a member of the staff of the German Hospital, San Francisco, vice Dr. Emil O. Jellinek.——Dr. Fred H. Bangs, San Jose, has been elected vice-president of the board of managers of the Agnew State Hospital for the Insane.——Dr. D. C. Strong, San Bernardino, has been re-elected physician and health officer of San Bernardino county, and superintendent of the county hospital.——Dr. C. S. Marvin has resigned as assistant superintendent of the Agnew State Hospital to accept a similar position in the Ukiah State Hospital.——Dr. Gustave Wilson, assistant superintendent of the Southern California State Hospital for the Insane, Patton, has resigned.

COLORADO

Farewell to Physician.—A farewell banquet was tendered to Dr. Sol G. Kahn, Leadville, by his brother physicians of the Lake County Medical Society, on the occasion of Dr. Kahn's departure for Salt Lake City.

Must Stop Practice.—An injunction is said to have been served on Dr. Alfred Freudenthal, Trinidad, restraining him from the practice of medicine during the life of a contract entered into by himself and Dr. John R. Espey, which expires in October, 1911.

Society Meeting.—The Powers County Medical Association held its annual meeting in Lamar July 20. The following officers were elected: president, Dr. Elmer E. Bartelt; secretary and treasurer, Dr. Jirah H. Kellogg, and censors, Drs. William A. Packard and the president.

Personal.—Dr. Samuel D. Hopkins, Denver, is taking a trip to the Orient.——Dr. Thomas E. Carmòdy, Denver, has been appointed surgeon-general of the National Guard of Colorado.——Dr. George H. Stöver, Denver, is reported suffering from *x*-ray cancer and his hands have been operated on recently.——Dr. Francis B. Rothrock, Colorado Springs, has returned from a trip around the world.

The Work of the Tuberculosis Home.—"The Oakes Home," an institution for the tubercular in Denver, now occupies a group of six buildings and has a capacity of 150 patients, and in the fourteen years of its existence has received 8,700 patients. Patients are received in all stages of the disease and at varying charges. Last year a workshop was opened where more than 50 patients have been employed at book binding, china painting, weaving, basketry and metal work. The products are sold at the workshop which is now-self-supporting. The funds were obtained by Rev. Frederick Oakes and the property has been deeded by him to the Episcopal diocese to be used in the care of tuberculous sufferers.

CONNECTICUT

Reception to Scotch Obstetrician.—Sir Alexander Russell Simpson, professor of midwifery in the University of Edinburgh, was the guest of honor at a reception at the Hunt Memorial Building, Hartford, June 28.

Commencement at Yale.—At the annual commencement exercises of Yale University Medical Department, New Haven, Dr. William H. Howell, dean of Johns Hopkins Medical School, Baltimore, delivered the doctorate address on "Medicine."

Personal.—Dr. Frank N. Freeman, traveling fellow in philosophy and psychology of Yale University, has been appointed instructor in educational psychology in the University of Chicago.——Dr. Oliver T. Osborne, New Haven, has gone to Europe.

Vasectomy in Connecticut.—The House of Representatives at Hartford passed a bill July 20, establishing in Connecticut the principle of providing against the increase of defectives by performing the operation of vasectomy on criminals and inmates of state institutions for defectives in cases wherein the physicians deem it wise that the breeding of other defectives be not permitted.

DISTRICT OF COLUMBIA

Hospital Officials to Meet.—The eleventh annual conference of the American Hospital Association will be held at Washington, D. C., September 21-24.

Commencement Exercises.—At the annual commencement exercises of the Georgetown University Medical School, held in Washington, a class of 15 was graduated. President Joseph F. Himmell of the university conferred the degrees and the address to the graduates was made by Dr. D. Percy Hickling.——The item in The Journal, June 5, relative to the change in the deanship of the Georgetown University was an error, as the change in deanship occurred in the George Washington University.

Personal.—Dr. Reid Hunt has gone to Europe.——Dr. Harvey W. Wiley, chief of the Bureau of Chemistry, has had conferred on him the Cross of the Legion of Honor by the president of France.——Dr. J. Steele Forsythe has been appointed physician in charge of a hospital of a Brazil railway company.——Dr. G. Lloyd Magruder, Washington, has returned from Europe.——Dr. John S. Fulton has been appointed executive secretary of the International Congress on Hygiene.——Dr. Francis Wilson has succeeded Dr. Joseph S. Wall as a member of the board of fire and police surgeons of Washington.——Dr. Thomas A. Lee has succeeded Dr. H. W. Moffitt, resigned, as superintendent of the Casualty Hospital, Washington.

ILLINOIS

Chicago

Personal.—Dr. Alfred D. Kohn has returned from Europe.——Dr. Joseph P. Smyth has been re-elected high medical examiner of the Catholic Order of Foresters.——Dr. and Mrs. William N. Senn, Dr. and Mrs. George E. Baxter, Dr. and Mrs. George F. Fiske, Dr. Corey H. McKenna, and Dr. and Mrs. Arthur R. Elliott have sailed for Europe.

Out-Door School for Tuberculous Children.—On August 3, the first out-door school for tuberculous children was opened on the grounds of the Harvard School, West Seventy-fifth street and Vincennes road, under the joint management of the Board of Education and the Chicago Tuberculosis Institute. The school at first will have thirty pupils, selected from children attending the public schools who are found physically subnormal, or predisposed to tuberculosis.

Addresses of Chicago Physicians Wanted.—Physicians in Chicago who have not already done so are asked to send to the American Medical Association their new street numbers—for two purposes: that The Journal may be correctly sent and that their addresses may appear correctly in the American Medical Directory which is now being printed. A blank was given on advertising page 40 of The Journal, August 7, and the matter was discussed editorially on page 463 of that issue.

Hospital News.—The board of directors of the Norwegian Lutheran Deaconess' Home, at a meeting, July 13, completed the arrangements for the new $75,000 hospital to be built adjoining the old home at Haddon avenue and Leavitt street.——A donation of $5,000 has been made by the Illinois Steel Company to the South Chicago Hospital, to be applied toward the payment of the indebtedness.——The Gil W. Barnard Hospital Association, organized and incorporated by prominent Masons of this city, is endeavoring to raise $200,000 for the establishment of a hospital.——Construction work has been begun on the new addition to Wesley Hospital which is to cost $125,000, and to accommodate about 180 additional patients. The new wing will be ready for occupancy in February next.——By the will of the late Augusta Mannheimer, widow of Dr. M. Mannheimer, $10,000 is bequeathed to the United Hebrew Charities for the benefit of the Michael Reese Hospital, with the suggestion that a contagious ward for children be maintained; $2,500 is bequeathed to the Alexian Brothers Hospital, and all Dr. Mannheimer's medical books are given to Rush Medical College, together with a bequest of $5,000 for the establishment of a library to be named after the testator's husband.

INDIANA

Refused License.—At a meeting of the State Board of Medical Examination and Registration, July 15, it was agreed by a unanimous vote not to reinstate Dr. Charles L. Landfair, Bluffton, whose license was revoked after the investigation of charges of criminal practice.

Personal.—Dr. Lewis N. Geisinger, Auburn, has been appointed secretary of the DeKalb County Board of Health, vice Dr. Jacob D. Casebeer, deceased.——Dr. Walter Baker, South Bend, has been selected to take charge of the Anti-Tuberculosis Society's fresh-air colony at Pottawattomie Park.——Dr. Minnietta Hervey, physician for the Home for the Friendless, Richmond, has resigned.——Dr. Erastus S. Fisher, Markle, is said to have been declared insane July 8.

IOWA

Physician Pardoned.—Dr. J. W. Crawford, Lamoni, convicted of the murder of Miss Maud Stone 4 years ago by a criminal operation and sentenced to imprisonment for twelve years in the state penitentiary, has been pardoned by the board of control because of evidence presented that the deceased was already suffering from the effects of a criminal operation when she consulted Dr. Crawford.

Personal.—Dr. Albert C. Moerke, Burlington, has been elected president of the State Board of Medical Examiners, vice Dr. Alfred P. Hanchett, Council Bluffs.——Dr. W. J. Neuzil has resigned as assistant surgeon of the Soldiers' Home, Marshalltown, and Dr. H. A. Newell has been appointed his successor.——Dr. William J. Heflin, Nora Springs, suffered a severe scalp wound in a collision between his automobile and a telephone pole July 24.——Dr. Edgar B. Henderson, Marengo, dislocated his knee by a fall, July 10.——Dr. Dill N. Pattison, Oelwein, has resigned as local surgeon of the Chicago Great Western Railway.——Dr. Charles S. Grant, Iowa City, has been detailed as surgeon of the Fifty-fourth Infantry, I. N. G., during its encampment this month.

KANSAS

College Wants Medical Department.—Midland College, Atchison, it is announced, will open a medical department by affiliating with Ensworth Medical College of St. Joseph, Mo.

Large Proportion of Convicts Tubercular.—The State Board of Health has just completed its tests among the 812 convicts in the state penitentiary, Lansing, and finds that 160, of whom 88 are white and 72 colored, show signs of tuberculosis.

Election.—At a meeting of the Jefferson County Medical Association held in Valley Falls, June 30, the following officers were elected: president, Albert D. Lowry, Valley Falls; secretary and treasurer, Frederick P. Mann, Valley Falls; censors, Drs. Edgar C. Rankin, McLouth, and Millard F. Marks, Valley Falls, and delegate to the state association, Dr. David D. Wilson, Nortonville.

The Antituberculosis Fight.—Dr. C. S. Emley, state lecturer, started on his tour against tuberculosis August 1. He is traveling over the state in a car specially equipped for the work, expects to visit every town in Kansas, and will remain in the larger towns for a few days, giving lectures and teaching the people what the state is endeavoring to do in its fight against tuberculosis.

Personal.—Dr. Valentine V. Adamson, Holton, has been elected assistant surgeon of the Fort Dodge (Iowa) Soldiers' Home.——Dr. John C. Lardner has been appointed city physician of Chanute, vice Dr. Fred R. Hickey.——Dr. Walter C. Palmer, Kansas City, has been appointed superintendent and physician-in-charge of the hospital at Hiawatha.——Dr. Henry M. Stewart, Hutchinson, has won a suit in which he was sued for $5,000 damages for malpractice.

KENTUCKY

No More Corner Pumps.—A resolution has been introduced in the general council of Louisville calling on the Board of Public Works to draw up an ordinance doing away with the town pumps and to substitute hydrants.

Personal.—Dr. W. H. Nuttall, superintendent of the Feeble-Minded Institute, Frankfort, has resigned, and has been selected by Dr. A. C. Nevitt as physician of the Eastern Kentucky Hospital, Lexington.——The names of Dr. John R. Wathen and Dr. MacCracken, were omitted from the list of the faculty of the University of Louisville, Medical Department.——Dr. William B. Doherty has been appointed a trustee of the Louisville Public Library.——Drs. W. Horace Witherspoon and Carroll P. Price have been elected members of the board of health of Harrodsburg.——Dr. George W. F. Rembert, superintendent of the sanatorium of the Kentucky Antituberculosis Association, has resigned.——Dr. William P. Drake, Rockfield, has succeeded Dr. Eldon N. Hall, Woodburn, as physician of Warren county.——Dr. Philip H. Stewart, Paducah, has been elected president of the board of health of McCracken county, and Dr. Horace Rivers, Paducah, health officer.

LOUISIANA

New Sanitaria.—The new Fenwick Sanitarium for mental and nervous diseases and drug and liquor addictions has been opened at Abbeville under the directions of Frank F. and W. G. Young.——Dr. E. Y. Ames has leased the Mulberry Grove Hotel from Dr. M. G. Marrero, Covington, and will convert the building into a sanatorium for tuberculosis.

Personal.—Dr. Ada Schwing Kiplinger will open a free clinic at St. Mark's Hall, New Orleans, in September.——Dr. C. Milo Brady, New Orleans, special medical inspector of the State Board of Health, has resigned.——Dr. Lester J. Williams has been elected mayor of Melville.——Dr. Yves R. LeMonnier has been elected surgeon of the Soldiers' Home of Louisiana, vice Dr. William P. Brewer, deceased.

MAINE

Graduation Exercises.—The graduating exercises of the Medical School of Maine, Brunswick, were held June 23, and a class of 18 was graduated. The oration was delivered by Hon. DeAlva S. Alexander, Buffalo, N. Y.——The senior class of the school has presented to the school an oil painting of Dr. Edward J. McDonough, professor of obstetrics.

Personal.—Dr. John G. Towne, Waterville, has been appointed junior assistant surgeon of the Second Infantry, Maine N. G., vice Dr. Frederick A. Chandler, Addison, promoted to captain.——Dr. Thomas U. Coe, Bangor, has tendered to the University of Maine a site for the proposed home for its college of law, and in addition offers to give $1,000 toward the building.——Dr. John M. Eager has succeeded Dr. Parker C. Kalloch as quarantine officer at Portland.

MARYLAND

Personal.—The residence of Dr. Mylar P. Sutliff, Somerset Heights, was destroyed by fire July 27, with a loss of $5,000.——Dr. William S. Welch has been appointed health officer of Annapolis.

Outbreak of Typhoid Fever.—An appeal has been received by the State Board of Health to aid in the eradication of an outbreak of typhoid fever in Kent county. The investigation of the board shows that 26 cases have occurred the cause of which has not yet been determined.

New Health Plans.—Dr. Marshall L. Price, the new secretary of the State Board of Health, proposes to ask the legislature for an additional appropriation of $25,000, to be used in overcoming the loss to the state from disease. Among the improvements proposed are the wholesale purchase of nitrate of silver, to be put up in especially prepared packages, and sold or given to nurses and physicians, to be used in cleansing the eyes of the newborn, and the purchase of large numbers of standard disinfectant cards with instructions how to disinfect houses where there have been infectious or contagious diseases.

Baltimore

Change in Editorship.—The *Bulletin of the Medical and Chirurgical Faculty of Maryland*, with the close of Volume I, changes its editor, Dr. Henry O. Reik retiring, and being succeeded by Dr. Emil Novak. The *Bulletin* is strictly a society organ, devoted to the interests of the state society and its component county and local societies.

Illegal Practitioner Sentenced.—Robert H. Darrah, convicted in March last for the alleged practice of medicine without a license, is said to have been sentenced by Judge Gorter to imprisonment for thirty days in jail and to pay a fine and costs amounting to $32.25. An appeal was ordered, and the defendant was released on bail of $1,000.

President Remsen Goes to California.—President Ira Remsen of the Johns Hopkins University started for California August 1, with the referee board of consulting scientific experts, to obtain information regarding the methods used in drying fruits, in order to decide the question whether or not the so-called "sulphuring" process renders fruit unwholesome.

Personal.—Drs. Harvey W. Cushing, Frank Martin, Thomas B. Futcher and J. George Schmelzer have sailed for Europe.——Dr. St. Clair Spruill has been appointed associate surgeon to St. Agnes' Hospital, and Dr. J. F. O'Mara assistant.——Dr. J. Mason Hundley has been appointed visiting gynecologist to St. Agnes' Hospital.——Drs. Edward L. Mellus and William S. Baer have returned from Europe.

MASSACHUSETTS

Personal.—Dr. Freeman A. Tower, recently superintendent of the State Insane Hospital, Worcester, assumed charge of the Burbank Hospital, Fitchburg, July 19.——Dr. Arthur T. Schoonmaker has been elected town physician of Westfield.

Medical Examiner Wins Case.—In the case brought against medical examiner Andrew H. Hodgdon, Dedham, by Elizabeth Morton, in which $50,000 damages were asked on the claim that the medical examiner was negligent in not ascertaining that the plaintiff was unable to leave her home, the jury decided in favor of the defendant.

MICHIGAN

County Hospital for Tuberculosis.—At the recent meeting of the Board of Supervisors of Marquette county, $15,000 was appropriated for a hospital for tuberculosis, to be erected on the county house farm.

Jury Disagrees.—In the case of Dr. G. K. Boyajian, Detroit, who shot and killed his nephew, April 30, the jury disagreed, four voting for acquittal and eight favoring a compromise verdict convicting the defendant, but asking the governor to pardon him and to provide adequate punishment for home despoilers.

Personal.—Dr. Simon M. Yutzy, instructor in osteology and demonstrator of anatomy in the University of Michigan, Ann Arbor, has resigned to take effect in September.——The new city physicians of Detroit are Dr. George F. Lavin, George H. Voelkner, Joshua Hanser, W. G. Kanter, Philander B. Taylor and Edmund Quandt.

Communicable Diseases.—During June there were reported in the state 97 cases of pneumonia, 216 of tuberculosis, 67 of typhoid fever, 177 of diphtheria, 35 of meningitis, 110 of whooping cough, 213 of scarlet fever, 841 of measles and 64 of smallpox. This shows a decrease in typhoid fever, meningitis and smallpox, and an increase in pneumonia, tuberculosis, diphtheria, whooping cough, scarlet fever and measles.

June Mortality.—During June, 2,608 deaths were reported, equivalent to an annual death rate of 11.9 per 1,000. Of the number, 408 were infants under 1 year of age, 159 children from 1 to 4 years of age, and 826 individuals aged 65 years and over. Among the important causes of death were tuberculosis, 222; violence, 186; cancer, 145; pneumonia, 94; meningitis, 45; diarrhea and enteritis of infants, 39; measles, 25; scarlet fever, 19; diphtheria, 16, and whooping cough and typhoid fever, each 15. As compared with May, a slight decrease is noted in the deaths from tuberculosis, diphtheria, scarlet fever, measles, whooping cough, pneumonia and enteritis, and a slight increase in the deaths from pneumonia, cancer and violence. There were 7 deaths reported during the month from tetanus.

MISSISSIPPI

Cocain Seller Fined.—Dr. Sherrod, Meridian, a colored druggist, is said to have been fined $100 and to have been sentenced to imprisonment for sixty days, on the charge of the unlawful sale of cocain.

The State Medical School.—The Medical Department of the University of Mississippi will open for its first session in October. Prospects point to a large initial attendance. The faculty has been selected with the exception of a demonstrator of physical diagnosis.

New Hospitals.—The King's Daughters' Hospital, Grenada, has been incorporated for $10,000. The organization is supported by the local branch of the King's Daughters. A tract of 20 acres near Laurel has been purchased for $3,000, and will be used as a site for a new hospital.

Do Not Want Names Used.—Hinds County Medical Society, at its recent meeting, adopted resolutions declaring it unprofessional to use physicians' names in connection with illnesses, accidents, operations, etc., and requesting the papers of Jackson not to mention names of physicians in connection with the treatment of any case.

Personal.—Drs. William R. Card and Stevens have been reelected associate physicians of the Mississippi Insane Hospital, Meridian.——Dr. Orson M. Turner, Jackson, has been appointed local surgeon of the New Orleans Great Northern Railway.——Dr. Nolen Stewart, Meridian, has been appointed professor of nervous and mental diseases in the Medical Department of the University of Mississippi, and Dr. William Krauss, Memphis, Tenn., has been appointed dean and professor of pathology.——Dr. Harvey F. Garrison, Seminary, has been reappointed health officer of Covington county.

MISSOURI

New Hospital.—A permit was issued July 28 for the erection of the St. Louis Skin and Cancer Hospital, a four-story, fireproof structure, to cost $85,000.

College Will Not Reopen.—It is reported that the Homeopathic Medical College of Missouri, St. Louis, has temporarily suspended and will not reopen for the fall session.

Personal.—Dr. Louis E. Bunte, St. Louis, has been appointed a member of the State Board of Health, succeeding Dr. John T. Thatcher, Oregon, term expired.——Dr. G. Wilse Robinson, Kansas City, has been appointed superintendent of the Kansas City General Hospital.——Dr. George W. Davis, St. Louis, has been appointed first assistant surgeon of the Freedmen's Hospital, Washington, D. C.

Declares Cars Insanitary.—In an official letter, July 28, the governor calls on the State Board of Health to make an investigation of the sanitary conditions of sleeping cars and coaches operated on the railroads of the state. He calls especial attention to the insanitary conditions of closets and washrooms, both in ordinary cars and sleeping cars, and also to the fact of the promiscuous expectoration in cars.

NEBRASKA

New College Buildings.—The John A. Creighton Medical College has commenced the erection of a new laboratory building adjoining the college building proper, to cost $60,000. The building will be four stories in height, will have a frontage of 72 feet on Fourteenth street, and will contain nine general and private laboratories, besides clinic and lecture rooms, etc.——Plans have been accepted for the proposed group of buildings of the College of Medicine of the University of Nebraska, Omaha. The estimated cost of the group is $1,500,000, which provides for nine buildings built about a quadrangle, with a hospital in the middle. The $1,000 prize offered for the accepted plans was awarded to Shipley, Rutan and Coolidge, Boston.

NEW HAMPSHIRE

Personal.—Dr. Gardner C. Hill, Keene, has resigned from the staff of the Elliot City Hospital, and Dr. Arthur A. Pratte has been appointed to fill the vacancy.——Dr. Servule St. Pierre, McGregorville, has been declared insane, and committed to the state hospital.

Society Meetings.—The Manchester Medical Society, at its annual meeting, held June 13, elected the following officers: President, Dr. Walter T. Crosby; vice-president, Dr. Noel E. Guillet; secretary-treasurer, Dr. Clarence O. Coburn, and censors, Drs. Gustavus B. Morey, Wellington A. Thompson, Zatae L. Straw, Clarence O. Coburn and Clarence W. Milliken. Votes of thanks were passed to the retiring president and secretary-treasurer.——Dr. Frank Blaisdell, Goffstown, president of the New Hampshire Medical Society, was the guest of honor at the sixth semi-annual meeting of the Grafton County Medical Society held at the Mary Hitchcock Hospital, Hanover, June 1.

NEW MEXICO

State Society Meeting.—The first meeting of the New Mexico Medical Society to be held in the southeastern part of the territory, will be held in Roswell, September 15 and 16.

County Society Organized.—Physicians of Santa Fe county met at Santa Fe, recently, and organized a county medical society to be affiliated with the state and national organizations. Dr. William S. Harroun, Santa Fe, was elected president; Dr. Frank A. Yoakum, Cerrillos, vice-president, and Dr. James A. Rolls, Santa Fe, secretary and treasurer.

NEW YORK

County Laboratory Wanted.—Physicians of Nassau county have filed a petition with the board of supervisors, asking that a county laboratory be established and a county bacteriologist appointed.

District Society Meeting.—At the annual meeting of the Fourth District Medical Society, held in Plattsburg, July 8, Dr. Dayton L. Kathan, Schenectady, was elected president;

Dr. Grant C. Madill, Ogdensburg, vice-president; Dr. Frederick K. Resseguie, Saratoga Springs, secretary (re-elected); and Dr. George H. Oliver, Malone, treasurer.

Personal.—Dr. J. Walter Wood, Port Richmond, was attacked and assaulted near his home, August 6.——Drs. Francesco G. Rossi, Utica, and George W. Miles, Oneida, have been appointed lecturers of the State Board of Health, and Dr. Martin Cavana has been designated as medical expert.——Dr. Fred D. Andrew, Rochester, has been designated as medical expert and Drs. George W. Goler and Montgomery E. Leary, Rochester, as lecturers of the State Department of Health.——Dr. George H. Beers, Ticonderoga, was thrown from his automobile recently, breaking three ribs.

New York City

Italians Organize Society.—The New York Italian Medical Society has been incorporated with Drs. Antonio Stello, Vincenzo Sellaro, Antonio Scaturro, Giuseppe Tomasulo and Antonio Tarditi as directors.

Building for Physicians.—A 12-story office building is to be erected at 124 Joralemon street, Brooklyn, to be known as Galen Hall and to contain 45 suites of offices for the exclusive use of physicians and dentists.

Personal.—Dr. Thomas Addis Emmet will be one of the speakers at the exercises commemorative of the Battle of Yellow Ford, in Chicago, August 15.——Dr. Morgan G. Cutler was seriously injured in an automobile accident in Council Bluffs, August 1.——Dr. William H. Nammack, Far Rockaway, has been reinstated as coroner's physician of Queen's Borough.——By the will of Mrs. Marie H. Crawford, Pittsfield, Mass., $50,000 and the estate in Sheffield, Mass., is bequeathed to Dr. Thomas H. Allen.

Buffalo

Personal.—Dr. Robert F. Sheehan, Jr., has been appointed professor of hygiene at the University of Buffalo, vice Dr. Henry R. Hopkins, appointed emeritus professor.——Dr. Herbert Hill has resigned as professor of chemistry, toxicology and physics.——Drs. Jane W. Carroll, Regina Flood-Keys and Amelia Earle Trant are spending the summer abroad.——Dr. Albert P. Sy has been appointed associate professor of chemistry and toxicology in the University.——Dr. John H. Pryor has been placed in charge of the dispensary of the Buffalo Association for the Relief and Control of Tuberculosis.——Dr. Ernest Wende, health commissioner, has recovered from his recent illness and resumed his duties.

OHIO

Personal.—Dr. Adolphus W. Foertmeyer has resigned as receiving physician to the Cincinnati Hospital, and Dr. Adam E. Schlanse has been elected his successor.——Dr. George A. Fackler has been made vice-president of the new health board of Cincinnati, Dr. Mark A. Brown, health officer, and Drs. Edward W. Walker and John H. Landis have been appointed members.——Dr. James W. Miller has left for Europe.

Additions to the Faculty.—The trustees of the University of Cincinnati have made the following additional nominations in the medical department: Dr. Shaler Berry, lecturer on medical jurisprudence; Dr. Marion Whitacre clinical instructor in medicine; Dr. John A. Caldwell, clinical instructor in surgery; Dr. Clifford Sater, clinical instructor in diseases of the chest; and Dr. Albert H. Freiberg, professor of orthopedic surgery and supervisor of clinics.

OREGON

State Tuberculosis Board Organized.—The State Board of Tuberculosis Commissioners, created by act of the last legislature, met in Salem June 9, and decided to utilize the present building of the Deaf Mute School, east of Salem, as a temporary sanatorium for tuberculosis.

Hospital Notes.—Two of the older hospitals of Portland are completing large annexes. By the first of the year the annex of St. Vincent's Hospital will be ready, and the annex of the Good Samaritan Hospital, including a roof garden, is almost completed.——The new Sellwood Hospital was opened July 2. The building has been erected at a cost of $15,000.——Dr. John F. Calbreath, Salem, formerly superintendent of the Oregon State Insane Hospital, has purchased the interest of Dr. Wilson D. McNary, in the Mount View Sanitarium, Portland, and the Glencoe Sanitarium.

Personal.—Dr. Ferdinand H. Dammasch has been elected assistant health officer of Portland, vice Dr. Parker, resigned. ——Drs. Allan Welch Smith, George B. Story and Rupert J. Chipman have been appointed members of the board of health of Portland, vice Drs. Andrew J. Giesy, Robert C. Yenney and George F. Wilson, resigned.——Dr. Charles A. Ault, Enterprise, was seriously burned by an explosion of spirits on a train, July 7.——Dr. Calvin S. White, Portland, is reported to be critically ill in St. Vincent's Hospital.——Dr. Cortez H. Wheeler has been elected health officer of Portland, vice Dr. E. C. Pohl, resigned.

SOUTH CAROLINA

Pellagra.—At the August 6 meeting of the Abbeville County Medical Society, held in Abbeville, pellagra was studied. Several patients with the disease were presented, and Dr. James W. Babcock, Columbia, and Surgeon C. H. Lavinder, U. S. P. H. and M.-H. Service, presented papers.

Infirmary Opens.—Fennell Infirmary, Rock Hill, was formally opened July 21. The institution contains 18 rooms for patients, together with the necessary operating, sterilizing and other rooms, and in the basement there are two commodious wards for colored patients. The infirmary is the result of years of work of Dr. William W. Fennell, who is surgeon in charge.

GENERAL NEWS AND COMMENT

Personal.—Dr. Milton J. Rosenau, director of the Hygienic Laboratory of the U. S. Public Health and Marine-Hospital Service, has been appointed head of the newly established department of hygiene and preventive medicine in Harvard Medical School, Boston.

Railway Surgeons Meet.—The Buffalo, Rochester and Pittsburg Railways Surgeons' Association met for organization in Rochester, July 20, and elected the following officers: President, Dr. A. Miner Straight, Bradford, Pa.; vice-president, Dr. William B. Johnston, Ellicottville, N. Y., and secretary, Dr. Spencer M. Free, Du Bois, Pa.——At the twenty-ninth annual meeting of the Lehigh Medical Association held at Delaware Water Gap, Pa., July 22, the annual address was delivered by Dr. William L. Rodman, Philadelphia, on the treatment of hernia, and the following officers were elected: President, Dr. Obediah H. Sproul, Flemington, N. J.; vice-presidents, Drs. Jonathan M. Wainwright, Scranton, William E. Gregory, Stroudsburg, H. Herbst, Reading, and Henry A. Grim, Allentown; secretary, Dr. Clinton J. Kistler, Leighton, and treasurer, Dr. Albert A. Seem, Bangor.

Medical Colleges and University Connection.—Several medical colleges have become more closely connected with colleges of liberal arts during the past two years and are more completely under the control of universities, which doubtless means better laboratories, better teachers, and the adoption and enforcement of higher standards. In some of these sweeping changes have been made. (1) The Medical College of Alabama is now the organic Medical Department of the University of Alabama. (2) The University of Southern California College of Medicine is now the Los Angeles Clinical Department of the University of California. (3) Tulane University Medical Department has formed closer connection with the University and now has the buildings for the first two years of the medical course on the university campus. (4) The new Ohio-Miami Medical College of the University of Cincinnati will be under the direct control of the university. (5) Toledo Medical College is now the Medical Department of the newly established Toledo University, the development of which will be watched with much interest. (6) Tennessee Medical College has become the organic medical department of the Lincoln Memorial University. (7) It is stated that the new Medical Department of the Universities of Nashville and Tennessee will receive strong support from the University of Tennessee.

CANADA

Council Election.—The elections for the council of the College of Physicians and Surgeons of Saskatchewan, which recently took place, resulted as follows: Dr. Stanley Millar, Battleford; Dr. A. McG. Young, Saskatoon; Dr. James T. Irving, Yorkton; Dr. A. E. Kelly, Swift Current; Dr. W. A. Thomson, Regina; Dr. Hugh E. Eaglesham, Weybourne; and Dr. Andrew W. Argue, Grenfell.

University-Hospital Agreement.—A new agreement has been entered into between the trustees of the University of Toronto and the board of governors of the Toronto General Hospital. The university has added the sum of $400,000 to the $300,000 contributed a few years ago, on the understanding that the hospital will build on the site now being prepared a new pathologic building for the uses of the medical faculty of the university, and grant certain rights as to the appointments of heads of services. The subscriptions for the new hospital now amount to $1,300,000, the university debentures to another $300,000, and the value of the site of the old hospital is placed at $300,000. The cost of the new hospital is put down at $2,200,000, which still leaves $300,000 which the trustees of the hospital have undertaken to raise, as a part of the bargain with the university. The chief professors or other heads in the faculty of medicine of the university are to be ex-officio heads of services in the hospital. Other appointments are to be made to the hospital staff only on the recommendation of a joint committee composed of eight members, four each from the hospital and university. In a few weeks the ground for the new building will be prepared. It will be thoroughly ploughed, disinfected and then left until the spring, when excavations will be commenced.

FOREIGN

To Warn Students Against Exploitation of Physicians.—The profession in Belgium held a congress recently to discuss merely practical questions connected with medical practice—the fifth annual congress of the kind. Van Pée urged the necessity for instructing newly graduated physicians as to the various traps set for exploitation of the medical profession, into which they are liable to stray in their ignorance. He suggested instruction during the medical course, but others advocated a warning pamphlet for graduates, setting forth the rights and duties of the medical profession and the dangers that threaten the young physician. The importance of cooperation between the organized charities and physicians, in order to restrict free medical care to those actually unable to pay for it, was emphasized anew and a number of methods discussed how to render this more practicable. The *Gazette Médicale Belge*, July 15, contains the discussions in full.

New Insane Asylum at Naples.—One of the largest insane asylums in Europe has just been inaugurated in the vicinity of Naples. Twenty-seven buildings in large grounds form this city for the insane on the Capodichino hills; it has accommodations for 2,000 inmates and the new asylum at Rome for 1,063. Professor L. Bianchi is in charge of the Naples asylum.

Epidemic of Psittacosis.—A correspondent of the *Gazzetta degli Ospedali*, July 25, states that twenty-three scattered cases of an atypical pneumonia have been observed at Zülpich, near Cologne, with four deaths to date. The infection has been traced to two small parrots, recently purchased, in the house of the person first affected. The other cases developed among friends and relatives from a distance who had attended her funeral. The streptococcus cultivated from the cases was apparently identical with a streptococcus found in all the organs of one of the parrots. A vaccine was made with the streptococcus which seems to have aided in the recovery of some of the later patients.

Jubilee Anniversaries in the Profession Abroad.—A number of well-known physicians in Germany have celebrated their fiftieth professional anniversary this summer, including B. Fränkel, the editor of the *Archiv für Laryngologie*, who has taken such a prominent part in the campaign against tuberculosis. THE JOURNAL described, Nov. 17, 1906, page 1664, the international historical laryngologic exhibition held at Berlin that month in honor of his seventieth birthday. Another prominent laryngologist also celebrated his jubilee anniversary last month, A. Lucae, of Berlin, the author of the vibratory sound treatment of sclerosis of the ossicles. The honors paid to Sir Felix Semon on his retirement were mentioned in THE JOURNAL recently, page 308. The list of *Jubilars* includes further W. Ebstein, the clinician of Göttingen, who seeks his recreation in the study of the history of medicine. The July number of *Janus* publishes a two-page bibliography of his important contributions to the history of medicine alone. Other celebrants are the surgeon, B. Bardenheuer, of Cologne, one of the leaders in treatment of fractures by extension; the physiologist and hygienist, J. Rosenthal, of Erlangen; K. Eberth, professor of pathologic anatomy at Halle; L. Hermann, whose "Physiology" is in its thirteenth edition, and A. Bilharz, brother of the discoverer of the distomum. Bilharz practiced in this country from 1865 to 1878. In Spain, the eminent professors and clinicians, J. Calleja, dean of the medical faculty, F. de Cortejarena and M. Iglesias, were presented with souvenir medals by the Academy of Medicine at Madrid; other medals were given five other members whose professional career has also passed the fiftieth milestone.

Eighth International Tuberculosis Conference.—This conference was held at Stockholm, Sweden, July 8, with the attendance large and the discussions fruitful. A *Festschrift* presented to the conference gives a résumé of what Sweden has accomplished in the campaign against tuberculosis, containing many of the articles read by Swedish authorities. Buhre reported the growth of the Swedish National Association against Tuberculosis which now has over 22,000 members to a total population of 5,250,000. It maintains a tuberculosis exhibition and has had 976 public lectures delivered at various points since the organization of the association five years ago. Pamphlets for school children and for recruits have been issued and distributed by the thousands as also a special pamphlet warning against undue dread of the disease. Stipends for postgraduate courses at tuberculosis sanatoria for physicians and nurses are provided, and special study made of inexpensive sanatoria and a number of such erected. A special tenement house was also built with flats of one or two rooms and kitchen, rented at reduced rates to working-men's families in which one or both of the parents are tuberculous. The tenants are given extra fuel to compensate for the heat lost by the required ventilation, and the children are given their dinners. Facilities for bathing are also provided free. The tenement in Stockholm proved such a success that a similar one has been erected in a country district. The healthy children of tuberculous parents are boarded out in the country, 246 having been thus provided for by the association and 87 by the poor authorities, while a special asylum has been erected for such children whose parents prefer institutional rather than foster family care for them. The sale of the special tuberculosis stamps has realized $71,000 to date.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, July 31, 1909.

Radium in Diseases of the Eye

As stated in previous letters considerable attention is being devoted to radium in the treatment of disease. The latest development is its application to diseases of the eye. At the Moorfield's Hospital (the principal eye hospital in this country) Mr. Arnold Lawson, an ophthalmic surgeon and Dr. Mackenzie Davidson, a radiographic expert, have tried it in diseases which usually proved obstinate or improved slowly under ordinary treatment, or else were of a virulent nature requiring drastic measures. So far only 17 cases have been treated, but the results are most encouraging. Most of the lesions were corneal ulcers, 4 were non-ulcerative affections of the cornea and one was episcleritis. After one application for 5 minutes to a hypopyon there was distinct benefit. The patient was a man aged 35, who gave a history of injury to the right eye. There was a deep ulcer and a gray infiltrated area 4 mm. in diameter and a large hypopyon. Twenty-nine milligrammes of radium were applied for five minutes and five days later the congestion was subsiding and the hypopyon had disappeared. Two days after a second application he was discharged practically cured. All the other cases did very well. Some punctate erosions gave equally encouraging results, as also did old cases of trachomatous pannus, except in one case in which increased vascularity followed the treatment.

The Imperial Cancer Research Fund

The seventh annual report of the Imperial Cancer Research Fund has been presented by Dr. Bashford, general superintendent, at a meeting of the general committee presided over by the Prince of Wales. Dr. Bashford claimed that the arduous work done by the fund in the past seven years had effected a revolution in the cancer problem. Seven years ago no one conceived it possible that portions of the mammalian organism could be kept growing for a period four times the length of life of the animal. The number of different tissues now being propagated separately made it possible that the majority of tissues might be so grown and segregated. In other words a living animal could be analyzed into many of its living component tissues.

Annual Meeting of the British Medical Association

The annual meeting of the British Medical Association was held at Belfast on July 23 to 31. Though the number of members who attended (about 700) was not large, the meeting from every point of view—scientific and social—was a great success. The comparative smallness of the attendance compared with that of the previous meetings was no doubt due to the fact that the meeting was held in Ireland at a city not very acceptable to the great English centers of population from which it must be reached by a sea voyage. The meeting took place in the University of Belfast, the spacious class rooms and halls of which provided ample accommodations for all the sections. At the meeting of the representatives of the various divisions of the association, many medico-political and medico-ethical topics were discussed. One, to which allusion has already been made in THE JOURNAL, is of particular interest. Dr. Kirby of Birmingham moved "that the advertisement of patent foods, proprietary remedies and the like in the *British Medical Journal* is calculated to authenticate in the eyes both of the medical profession and of the public, the preposterous and often mendacious claims of the vendors, and that present condition of the advertisement pages is, in this respect, not creditable to the association." Dr. Kirby denounced many of the remedies advertised in the *British Medical Journal* as almost quack remedies, defining these as remedies of which the exact composition is not declared and which are widely advertised in the lay press. He held that the fact of such advertisements appearing seemed to the public to authenticate all that was said about them. The discussion revealed some divergence of opinion. While some members warmly supported the resolution and protested against the "prostitution of the pages of the *Journal*" by such advertisements, others held that the association could not give assurance of the veracity of every line that appeared in the advertising pages and that the fact of an advertisement appearing did not carry any sanction. Then the question was raised what would the carrying out of the proposal cost the association? The treasurer said that the *Journal* already refused many advertisements and that this cost them about $5,000 a year. He held that there was very little in the advertisements to complain of. Finally as compromise a motion was carried that the council instruct the *Journal* and finance committee to appoint annually a subcommittee for the revision of advertisements; that no advertisements be accepted until they have been approved by the subcommittee; and that the subcommittee shall not allow any advertisement to appear which contains misleading or exaggerated statements, nor any advertisement of any preparation which is advertised elsewhere than in the medical press as a remedy for any morbid condition, and is of such a character that its use demands medical supervision or which is advertised anywhere in misleading or exaggerated terms.

The president, Sir William Whitla, paid a tribute to the first occupant of the chair of medicine in the University of Belfast, created in 1836, Dr. Henry Macormac, father of Sir William Macormac, and "the father of the open-air treatment of consumption." In his works on "Consumption" published in 1855 he insisted on the influence of impure or rebreathed air as a cause of tuberculosis. But no one believed him; the discovery of his genius required half a century for its acceptance. Sir William criticized severely the present system of medical education. The number and extent of the subjects now placed in the medical curriculum were so great that the brain of the student failed to expand in assimilative power with the growth of advancing science.

Action Against a Hospital for Injury During Operation

In The Journal of May 15, page 1592, has been reported an extraordinary action by a physician against the governors of St. Bartholomew's Hospital. He alleged that while being examined under anesthesia his arms were allowed to hang over the sides of the table; that one was bruised by being pressed upon by the operator or some other person and that the other was burned by a hot water bottle; that the result was traumatic neuritis of both arms which paralyzed him and prevented him from following his profession. As he produced no evidence showing that he was injured in this way the judge refused to put the question of negligence to the jury and also held that even if there was evidence of negligence the governors were not liable for the action of their staff. The case then came before the court of appeals and was again dismissed.

PARIS LETTER

(From Our Regular Correspondent)

Paris, July 29, 1909.

Preservation of Medicinal Plants

The Academy of Medicine heard a report by M. Guignard, director of the Superior School of Pharmacy, on a work by MM. Perrot and Goris in regard to the sterilization of medicinal plants. It is well known that most plants lose a great part of their properties along with their freshness through chemical action. It is of importance then to arrest this chemical action as soon as the plants are gathered. Perrot and Goris treat the plants in an autoclave in the presence of alcohol vapors, after which the dry leaves preserve without modification the physiologic properties that they have in the fresh state. Experiments have been made chiefly on digitalis leaves.

The Instruction of Abnormal Children

The question of the instruction of abnormal and backward children, which for some years has been occupying physicians and educators, has just been brought before the Superior Council of Public Instruction. The latter has decided that in order to obtain certificate of fitness to teach backward children candidates will have to undergo a year's probation in a special establishment, designated by the Minister of Public Instruction, and affording opportunity to study at first hand the best means for attracting the attention of backward children and of drawing out their intelligence.

Prescription Clerks

An energetic campaign is now being carried on by the association of prescription clerks against the too long hours of work. Compelled to work fourteen to sixteen hours consecutively, often without a night service to assure them an opportunity to rest, the prescription clerks maintain that the situation is dangerous for the public itself, prescriptions put up under such conditions being liable to accident. The association has passed a resolution demanding a better regulation of their work by the closing of the laboratories at 8 p. m. and the creation of night municipal pharmacies.

Monument to Professor Liégeois

The tragic death of Professor Liégeois, who with Liebeault, Bernheim and Beaunis, founded the famous "school of Nancy," and who was the first jurisconsult to study the application of hypnotism and suggestion to criminal law and to legal medicine, was mentioned about one year ago (The Journal, Sept. 12, 1908, li, 929). A committee composed of the colleagues, friends and pupils of Liégeois has just been formed to erect to his memory a monument at Bains-les-Bains (department of the Vosges) at the spot where the scientist was killed by an automobile.

The Potain Prize

The Academy of Medicine has just been authorized to accept a legacy of $5,000 (25,000 francs), the accumulated interest of which for the three past years will serve to found a perpetual triennial prize in honor of the illustrious clinician who died a few years ago and which will be awarded to the author of the best work on clinical medicine which has appeared during each triennial period.

Election of Two Foreign Associates of the Academy of Medicine

In its session of July 27 the Academy of Medicine chose Drs. Hansen of Bergen and Morisani of Naples as foreign associates.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, July 22, 1909.

Cultivation of Spirochæta Pallida

The attempt to cultivate the *Spirochæta pallida* so as to demonstrate its etiologic importance by artificial infection of animals is continually being made and more favorable results appear to have been obtained. In the last number of the *Deutsche medizinische Wochenschrift*, Schereschewsky reports the continuation of his culture experiments in Neisser's clinic. He has succeeded in obtaining cultures of the spirochete, on horse serum, from primary affections of the fetal syphilitic spleen and blood and has been able to continue the cultivation to any desired number of generations. In the original cultures of the first few days the type of *Spirochæta refringens* is found almost without exception, but in the later generations and in the older original cultures the forms correspond to *Spirochæta pallida*. Animal experiments have, however, remained unsuccessful. Professor Mühlens has reached the same results and his work has been confirmed in the institute for infectious diseases. In the latter institute animal experiments with the pure culture of the spirochete are being carried on.

Personal

Professor Steyrer, first assistant of Professor Kraus in Berlin, has been chosen as the successor of Professor Minkowski for the position of director of the medical clinic at Greifswald.

The director of the medical clinic at Freiburg, Professor Bäumler, has resigned on account of age. He is succeeded by the previous director of the medical policlinic, Professor de la Camp. Professor Bäumler received the freedom of the city of Freiburg on the occasion of his resignation.

Professor Czerny of Breslau has received a call to the newly established chair of children's diseases in Strasburg. Professor Garré of Bonn has been given an honorary doctor's degree by the University of Geneva. Garré was born in Switzerland.

Physical Character of Recruits for One-Year Volunteer Service in the German Army

To obtain some statistical data with reference to the influence which the higher schools exercise on the physical development of the pupils, the military authorities determined in 1904 that, for every young man who appeared for enlistment in the one-year voluntary service (generally at the age of 19 to 24), a card should be filled out in which a number of questions regarding the condition of the volunteer's health should be answered. In this way, data were obtained regarding 80,454 recruits, from 1904 to 1906. Schwining and Nicolai, two military physicians, have published an article based on this material, giving very interesting results. The applicants for the one-year volunteer service as a rule show a somewhat higher degree of fitness than the other military recruits. The most unfavorable physical condition is presented by the pupils of the gymnasia, then follow the pupils of the technical gymnasia, technical schools and upper technical schools (*Realgymnasiasten, Realschüler, Oberrealschüler*).

If we take into consideration the time that passes between leaving school and enlistment, it appears that those who have had the shortest term of schooling show the greatest fitness and their number diminishes constantly the longer the school term; and, moreover, the number of suitable recruits diminishes in a still greater degree the longer the time that has elapsed since leaving school till the time of examination. While without doubt the latter fact is partly accounted for by the circumstance that weakly individuals, or those affected with other bodily defects, wait longer for volunteering for service than strong and sound men, still, in the opinion of the authors, the time since school of itself must exercise an especially unfavorable influence on physical development. The proportion of the more serious degree of unfitness increases with the length of the school period. Likewise, the gymnasia and technical gymnasia are distinguished from the other classes of schools by the higher degree of unfitness of their pupils. There are proportionally more tall individuals among the one-year volunteers than among the other recruits. The general degree of fitness increases on the average with increasing height. In general, the degree of fitness is lower among short recruits; but in four Bavarian provinces the conditions are exactly reversed. Among former pupils of the gymnasia, 47.8 per cent. had defects of vision; 36.9 per cent. were myopic. The number of those with defects of vision increase in the gymnasium pupils with the duration of their attendance at school. In general, 44.1 per cent. of the one-year volunteer recruits have defects of vision; 33.5 per cent. are shortsighted.

The Leipsic League

A report of the activity of the Leipsic League for the last year was made at the general meeting held in Lübeck, which gives a satisfactory account of the work accomplished by the executive committee. The league has now 22,440 members; nearly 2,000 members have joined within the last year; certainly a remarkable success when it is considered that the yearly dues are $5 (20 marks), times are hard for our profession, and the social relations of our profession are in general unfavorable. The various items of mail matter in the course of a year amount to more than half a million. Membership on the executive committee in general is honorary; only the two secretaries receive a salary, as they must naturally devote their entire attention to the league. The league includes 10 national or provincial leagues, 128 sections, 10 auxiliary groups. These leagues are directed by 1,100 superintendents. For purposes of agitation and at times of economic struggles, speakers are sent by the committee to the place affected. The committee maintains a bureau for legal information and a bureau to secure places for assistants, substitutes and ship's surgeons. Last year 2,227 places of the first two classes were provided and 244 of the latter. The league also carries on its own book business, retails books and publishes a physician's calendar. The committee also maintains a correspondence department in which communications to the political medical press are reprinted, and a bureau, sustained by the voluntary contributions of physicians, for the assistance of the needy widows of physicians. The receipts for the last year amounted to $4,440 (18,500 marks); the resources on hand amount to $3,600 (15,000 marks); the expenditures were $4,560 (19,000 marks). The largest pecuniary transactions of the committee were necessitated by the conflicts with the *Krankenkassen;* in this work sometimes physicians who threatened to appear as strike-breakers were dissuaded by money contributions and in other cases members who were compelled to give up their positions with the *Krankenkassen* in consequence of the strike were assisted pecuniarily until the end of the struggle. In this way large sums were expended which were secured not only by the yearly dues of the members, but also by voluntary contributions from German physicians.

VIENNA LETTER

(From our Regular Correspondent)

Vienna, July 28, 1909.

The Antimalaria Campaign in Austria

In southern Austria malaria was until recently so prevalent that energetic measures had finally to be adopted. In 1907 and 1908 the sanitation of the entire province of Dalmatia was effected. In the first year 212 towns and villages, with 89,000 inhabitants, were dealt with. Twenty-three physicians and 359 attendants were engaged all the year round. All suspected ponds and cisterns were filled up and a thorough examination of all affected persons with a routine treatment instituted. There were 3,400 persons with chronic malaria and 6,417 fresh cases, or 43 per cent. of the entire population, to be treated. In only 5,750 cases no swelling of the spleen could be discovered. Quinin and iron were given for fifteen days in full doses in chronic cases, and quinin alone in acute cases. No after-treatment was adopted. In 20 per cent. there was recurrence; this was treated by the same method. No prophylactic doses were distributed.

Altogether, 630 kilos (about 1,700 pounds) of quinin were used, or about 15 gm. (half an ounce) *per capita.* A rapid diminution of serious cases was noted; while formerly more than 10 per cent. of all patients had spleens reaching 4 inches or more below the costal arch the number soon fell to 3 per cent. The expense was very low, $50,000. In 1908, of 113,000 new subjects, only 4,350 were found without swellings of the spleen. In 18 per cent. there was recurrence after treatment. The amount of quinin distributed was 725 kilos, or over 1,900 pounds, an average of 14 gm. per person, as 39 per cent. of the population were affected. In 1909, the remaining district, with a population of 220,000, will be dealt with, and thus the whole country will be rid of the disease.

Pharmacology

PAPAYANS BELL

Report of the Council on Pharmacy and Chemistry

The following report of a subcommittee was submitted to, and adopted by, the Council and its publication directed.

W. A. Puckner, Secretary.

Papayans (Bell) made by Bell & Co., Orangeburg, N. Y., is said to consist of the "digestive principle obtained by our own exclusive process from the fruit of *Carica papaya*, combined with willow charcoal, chemically pure sodium bicarbonate and aromatics." The following statement appears on the package: "For the treatment of dyspepsia, flatulence, nausea, vertigo, hyperacidity, palpitation and other symptoms of indigestion and the vomiting of pregnancy. Peritonitis, cholera morbus, alcoholism and seasickness." "Digests every variety of food, removes every symptom of indigestion, restores the entire digestive tract to a normal condition." The dosage is recommended as follows: "From one to three tablets before meals, or two hours after eating. In severe cases, three tablets dissolved in hot water and repeated as necessary."

A circular which accompanies the package details the therapeutic virtues of the preparation and contains what purports to be extracts from medical journals, in which Papayans is recommended.

Examination of specimens purchased in the open market showed them to contain the following ingredients: Charcoal, sodium bicarbonate, ginger, saccharin and oil of gaultheria. As the product is said to contain papain, the presence of enzymes was tested for, with the result that it was found to possess neither proteolytic nor amylolytic properties. The results of our examination are in accord with the results obtained by a member of the Council, who examined the product independently, and who writes:

"We have made some extended tests with Papayans Bell, and find that the tablets consist essentially of sodium bicarbonate and charcoal, with a little flavoring matter. We find no digesting power for starch or egg albumin. At any rate, no appreciable change follows in the albumin in three hours, and no conversion to sugar in the same time, or change of starch to a point where the iodin reaction is weakened. The product seems to be practically inert."

It is recommended that Papayans Bell be refused recognition, and that publication of this report be authorized.

Comment: It will be remembered that two other products of Messrs. Bell & Company have been discussed in this department: Salacetin (Bell)[1] and Sal-Codeia (Bell)[2]. Salacetin was examined with several "synthetics" which all turned out to be mere acetanilid mixtures. Salacetin, advertised as "a combination, with heat, of Salicylic and Glacial Acetic Acids and Phenylamine" when examined "was found to be a mixture and to contain the following ingredients approximately in the proportion given: Acetanilid, 43; sodium bicarbonate, 21; and ammonium carbonate, 20." Sal-Codeia (Salacetin-Codein) therefore, would be the same with codein added.

Papayans (Bell) seems to be consistently fulfilling the life-history of the average nostrum. Made of well-known drugs and invested by its manufacturers—or exploiters—with virtues absurdly disproportionate to the known properties of the alleged constituents of the nostrum, the preparation was introduced to the world *via* the medical profession. With the help of thoughtless physicians, aided by a skillful and aggressive advertising campaign and augmented by the "free sample" device, the business grew and prospered. The bottles *with the name and address of the company blown in the glass* and with the varied therapeutic indications for the nostrum printed both on the label and on a circular in which the bottle is wrapped, have carried the manufacturer's message to the drug-taking public.

Apropos of this point, the recent "literature" contains what purports to be endorsements of the nostrum by medical journals. Thus there is quoted from the *New York Medical Journal*, Jan. 2, 1909, in part, the following recommendation: ". . . we venture to suggest to our readers who have not tried this remedy that they prescribe one *original sealed package* of Papayans (Bell) and that they carefully note the results from its use." [Italics ours.—Ed.] Having seen an "original sealed package" we believe that we can predict the "results from its use." On any patient not mentally unbalanced, the result would be that the next dose of Papayans (Bell) he thought that he needed would be purchased from the druggist direct.

That such results are not hypothetical is evidenced by the statements of the exploiters of Papayans (Bell) that "the annual sale now exceeds four hundred million tablets." Assuming this statement to be true, it would be necessary for every physician in the United States to prescribe over three thousand of these tablets every year—if they reached patients only through the physician! The company's own figures indicate that the time is about ripe to take care of this vast army of self-drugging laymen and recent circular letters seem to recognize it. The physician is notified that druggists are now furnished with Papayans (Bell) "in sealed packages of thirty and one hundred tablets." The medical man is *told that the firm has "not forgotten the days* when physicians' orders made our success possible" and it says *it is* "sincerely grateful to the doctors who gave us orders in the days when we were struggling for recognition." This tacit admission of the value of the physician as an unpaid agent for nostrum houses should be given thought by those physicians who prescribe such preparations.

While, so far as we know, Bell & Co. have not yet advertised in the daily press, they are not averse to furnishing the laity with samples when requested. An Ohio physician sent us the following letter received by a young woman who had written asking for samples:

> Miss X—— Y——,
> Z——.
>
> Dear Madam: As requested, we are mailing you sample of our Papayans (Bell) for Indigestion
>
> If a sufferer from Indigestion, we want you to give it a thorough trial as directed and note remarkable results that we believe you will get from its use.
>
> Kindly write us if you are unable to obtain it from your local druggist, as it is stocked by nearly every good drugstore in the United States. Yours truly,
>
> Bell & Co.

Evidently Bell & Co., while admitting that their financial success is largely due to the kindly, though misguided, efforts of physicians, are not going to let a little thing like loyalty to the medical profession interfere with a possible sale of their tablets.

THE L. D. JOHNS COMPANY

A discussion of the methods of Bell & Company would not be complete without reference to a concern which seems to be closely connected with it: the L. D. Johns Company, whose "only product" is a sugar-coated laxative tablet. Regarding the "sugar coated" tablet, a visitor at the place of business of Bell & Company and the L. D. Johns Company, wrote: "These companies apparently are not in possession of any tablet coating machines and in questioning on this point stated that some of their tablets were sent out to be coated." There is a sameness regarding the claims for the laxative tablets of the two companies that might lead *one* to *suspect* that the same individual prepared both. For instance:

Cascarans (Bell)	Dr. John's Tablets
"Taken as directed, it permanently removes the great majority of cases of habitual constipation."	"Taken as directed . . . permanently remove the great majority of cases of habitual constipation, *torpid liver* and sick headache."
" . . . a harmless vegetable preparation."	"A harmless vegetable remedy."
" . . . for the removal of pimples, yellowness and greasiness of the skin . . ."	" . . . removes pimples, blotches, sallowness and greasiness of the skin . . "
" . . . one tablet at night, one night and morning, or, in severe cases, one three times a day, gradually decreasing the frequency of the dose as improvement permits."	"One at night, one night and morning, or, in severe cases, one three times a day. Gradually decrease the frequency of the dose as improvement permits."

According to a leaflet sent out with samples by the L. D. Johns Company, the company is capitalized for $500,000, divided into 50,000 shares at $10.00 each; these shares are sold to those physicians who will agree "to prescribe the tablets at every suitable opportunity, to introduce them to other physicians" and "to promote their sale in every ethical way"! If the list of physicians' names and addresses which the company sends out as comprising the eastern stockholders is to be relied on, it would seem that many medical men are promoting their sale. In prescribing it is, of course, "necessary to specify 'Dr. Johns' Tablets No. XXX (*Original bottle*).'" As the name is on the bottle, it is not unbelievable that, as the company says in its prospectus, because of "our method of advertising, a large and very profitable business is being created." That the L. D. Johns Company expects to profit by the self-drugging which this method of prescribing fosters is evident:

> "Physicians not stockholders in this company suffer from the continual refilling of their prescriptions and from the recommendation of the *preparation prescribed by patients* to others. [Italics ours.—Ed.] Our stockholders *benefit* by the refilling of their prescriptions and by these recommendations."

Put baldly the case amounts to this: Physicians who prescribe "Dr. Johns' Tablets" not only are likely to foster self-drugging, but they will reap dividends therefrom. Truly a nice business to be in!

While Bell & Company and the L. D. Johns Company are said to be entirely distinct, they are to be found at the same address at Orangeburg, New York, and as will be seen, the officers of the two companies are more or less related.

BELL & CO.		L. D. JOHN CO.

EXPLOITING THE PROFESSION

Nostrum promoters have two simple ways of "working" the medical profession. The first—and the more profitable—is, by lavish distribution of free samples, to get physicians to prescribe the blown-in-the-glass "original package" with the inevitable result of large sales direct to the laity. By the second method, which is merely a modification of the first, the physician furnishes the capital for floating the nostrum and then takes his share of the resulting profits. There may not be quite as much money in the second method for the promoter, but then the risks are correspondingly less. If the firm fails, the stockholders are the losers; the promoter is not necessarily "out" anything. From a commercial standpoint, a combination of the two methods is, of course, ideal.

MADAME YALE'S PREPARATIONS

The Latest Series of Nostrums Officially Demonstrated to be Humbugs

A few of the convictions under the Food and Drugs Act have been noted in The Journal, April 24, 1909. One of the latest "notices of judgment" emanating from the Board of Food and Drug Inspection at Washington refers to the misbranding of a number of preparations marketed by one Maude Yale Bishop Wilson, of New York City, who rejoices in the euphonious trade name of "Mme. Yale."

MME. YALE'S EXCELSIOR SKIN FOOD

One of the preparations was known as "Mme. Yale's Excelsior Skin Food" and was advertised as "a marvelous nourishing product that feeds through the pores of the skin. . . . Can not be duplicated as it is compounded by Madam Yale personally and protected by a chemical secret. . . . The only genuine skin food in the world. It is absolutely guaranteed to remove wrinkles and every trace of age from the face of all who use it."

The government chemist analyzed this "marvelous" product and found that "it consisted of 76.5 per cent. of vaselin which was mixed with fixed oil or fat and zinc oxid, colored with a pink dye and perfumed."

MME. YALE'S EXCELSIOR FRUITCURA

Mme. Yale's Excelsior Fruitcura is, according to madam, herself, "primarily 'Woman's Tonic,' a cure for every ill to which she is sexually heir from Infancy to Old Age. It is Nature's prompt omnipotent Restorative—a Specific for the Generative Organs—Fruitcura cures the so-called 'Incurable.' It is an Elixir of Life—It prevents and cures Prolapsus or Falling of the Womb and all Displacements of Womb or Ovaries."

This also was analyzed and found to consist "of 76.97 per cent. of volatile matter (largely water with 16.66 per cent. of alcohol by volume), 29.71 per cent. of sugar and small quantities of plant drugs."

MME. YALE'S FERTILIZER TABLETS

Still another preparation was "Mme. Yale's Fertilizer Tablets," which were recommended as "A Cure for Obesity" and "A specific for curing . . . all Gastric troubles." The government chemist said that "the tablets were very largely composed of charcoal compounded with potassium bitartrate and sugar."

MME. YALE'S EXCELSIOR HAIR TONIC

"Mme. Yale's Excelsior Hair Tonic" was found to consist "of 15.56 per cent. of alcohol by weight, 82 per cent. of water and small amounts of glycerin, perfumed with bergamot oil." If "Mme. Yale" is to be believed, this mixture of alcohol and glycerin "stops hair falling, cures and prevents Dandruff and all Scalp Diseases and overcomes any hereditary tendency to Baldness or Grayness."

MME. YALE'S EXCELSIOR COMPLEXION BLEACH

Another of the Madam's preparations was claimed to "remove moth patches and all skin discoloration" and in addition "creates natural beauty." But that is not all: "It purifies the entire skin, penetrating its remotest recesses—invigorates nerves, muscles and ligaments—makes the flesh firm and searches out and expels every impurity. Its compound is a chemical secret known only to Madam Yale."

No longer is it a secret for we read "the analysis of the . . . Complexion Bleach, disclosed that it was mainly a saturated solution of borax in orange flower water."

MME. YALE'S ANTISEPTIC

"Mme. Yale's Antiseptic" was also alleged to possess remarkable properties. "Used in the bath is a sure cure and preventive of . . . all diseases of the skin and scalp. It is a perfect Disinfectant, Deodorant, Germicide, Prophylactic and Antiseptic, destructive of all disease germs, bacilli and all bacteria of micro-organisms [*sic*] yet it is 'non-toxic.'" In addition it was a "Sure preventive of typhoid fever."

This destroyer of "all bacteria of micro-organisms" was analyzed by the Bureau of Chemistry and found to consist "of 97.6 per cent. of volatile matter (16.96 per cent. of alcohol by weight, 4 per cent. of formaldehyd, and water), 2.37 per cent. of boracic acid and aromatics."

MME. YALE'S BLUSH OF YOUTH

"Blush of youth is refreshing as concentrated dew, pure as purity—It overcomes all inactivity and imperfection of the skin and underlying structure; spiritualizes the expression and gives the countenance the glow, luster and beauty of Childhood and preserves the morning of life indefinitely." "Blush of Youth" it should be explained is but one more of Mme. Yale's marvelous preparations.

For those who, like Ponce de Leon of old, are looking for something in this line, the analysis of the government chemist may prove interesting: "Mme. Yale's Blush of Youth . . . consisted of 56.15 per cent. of volatile matter (6.30 per cent. of alcohol by weight and 49.85 per cent. of water, colored with a cold tar dye and perfumed), and about 43.85 per cent. of glycerin." This would seem to show that the long-sought fountain of eternal youth consists essentially of a mixture of water and glycerin, with a dash of alcohol.

These various preparations, comprising in all over eighty dozen packages, had been shipped to S. Kann Sons & Co., Washington, D. C., by "Mme. Yale." They were seized by the government and samples of the various preparations were subjected to analyses in the Bureau of Chemistry of the Department of Agriculture. By comparing the analyses with the statements on the labels and circulars enclosed with the several preparations "it was apparent that these statements were false, misleading and deceptive and the preparations misbranded within the meaning of Section 8 of the Food and Drugs Act of June 30, 1906." These preparations of "Madam Yale's" thus furnish the latest addition to the government's galaxy of officially demonstrated humbugs.

Sanitariums and the Acetanilid Habit

To the Editor:—I enclose herewith a "form" letter and question blank which I received recently from St. Louis. I may be entirely too wary but I am suspicious that this is a collection of "statistics" to combat the work of the medical profession in educating the physician and the laity in the harmfulness of acetanilid and similar preparations.

G. H. Benton, M.D., Chester, W. Va.
Sterling-Worth Sanitarium.

Comment: The letter which Dr. Benton encloses is in facsimile form and purports to come from Uriel S. Boone, M.D., of St. Louis, who states that he is "preparing an exhaustive article for publication in a leading medical journal" on the question, "Is acetanilid a habit-forming drug?" To obtain the necessary data Dr. Boone is "writing to every hospital and sanitarium in the United States." Examination of the question blank which accompanies the form letter discloses the fact that information is wanted regarding not acetanilid alone, but also antipyrin and acetphenetidin (phenacetin). The last question asked runs as follows:

> "If your records [of cases of habitual use of these drugs] are incomplete, would you allow a reputable physician to investigate the above mentioned cases so that he could write with positiveness about them, and, if necessary, *make oath to the truth of his report?*" [Italics ours.—Ed.]

Dr. Boone opines that the recipients of his queries "may hesitate to answer" the question just quoted, but he trusts that its importance will be evident when he explains that "it is currently reported that the manufacturers of acetanilid, phenacetin, etc., *have decided to prosecute all libelers of these drugs*" [Italics again ours.—Ed.] and he wishes to make no statement that he "can not substantiate under oath." Surely the life of the collector of medical statistics is unusuallly hazardous.

For the purpose of aiding Dr. Boone in his arduous search for truth on the "much mooted question, 'Is acetanilid a habit-forming drug?'" we direct his attention to a work that should prove of invaluable assistance. We refer to Bulletin 126 of the Bureau of Chemistry, entitled "The Harmful Effects of Acetanilid, Antipyrin and Phenacetin." This interesting study to which we have previously (THE JOURNAL, July 24, 1909, p. 303) called attention, records 112 cases of the acetanilid-habit. Of this number, at least 50, or 44.6 per cent. of the cases were those of patients who took proprietary preparations of the drug. From this we would not wish to give any bias to Dr. Boone's statistics. We hardly expect, however, that such will be the case. Dr. Boone's name appears as the author of an article entitled "A Therapeutic Study of Antikamnia and Heroin Tablets"—an article that has been very extensively "quoted" and has been sent out in its entirety by the Antikamnia Chemical Company. Under these circumstances we may be forgiven if we venture the opinion that Dr. Boone is not likely to be unduly prejudiced against "headache tablets" in general and fake "synthetic" coal-tar mixtures in particular. We await with breathless interest the appearance of Dr. Boone's "exhaustive article" and we must confess to some degree of curiosity regarding the name of the "leading medical journal" in which these invaluable data will appear.

Correspondence

The Teaching of Obstetrics

To the Editor:—Interest in the plan which has been advocated for so many years by the American Academy of Medicine looking to a higher standard of medical education is now being intensified by the report of the Carnegie Foundation concerning various schools throughout the country. The requirements of our state boards of health must appeal to the graduate himself. Dr. Arthur D. Bevan's splendid work in the Council on Medical Education and the rapid advance in the requirements of the Association of American Medical Colleges are hopeful signs of the times. All these efforts, it is to be hoped, will soon be focused in a uniform course of study in the various colleges which will harmonize the various teaching faculties to the benefit of the student.

No phase of the very intricate question of division of time in the curriculum of the medical school of to-day is of more interest to the student nor more likely to be unappreciated by the faculty than that pertaining to the relative value of obstetrics as compared with gynecology and surgery. A knowledge gained by correspondence with a number of the eminent teachers of obstetrics and gynecology shows a remarkable unanimity of opinion among them that obstetrics in our colleges does not cover the ground it does abroad nor what it should to give the student a real *Frauen Klinik* instruction; but at present the trend of the average student in the clinical years is to over-emphasize the more spectacular surgical clinic and to minimize research work and clinical diagnosis which must be the foundation of basic principles for the subsequent results in actual bedside practice.

At the recent conference of the subcommittee on curriculum of the clinical years of the Association of American Medical Colleges, held in Atlantic City, the importance of a just distribution of the 2,000 hours of the clinical years was made clear. Professor Reuben Peterson, of Ann Arbor, and I, to whom the subject of obstetrics and gynecology was assigned by President Hoxie, are trying to obtain an expression from the heads of the departments of surgery, gynecology and obstetrics, relative to the proper place of each in the curriculum, and the line of demarcation between them on hazy subjects, as a basis for our report to the next annual meeting of the association, in Baltimore, next March.

When the student is taught principles of diagnosis, and operative surgery is made a postgraduate subject, the young practitioner will more nearly appreciate his instruction. A physician of ten years' experience, a graduate of an Eastern college, came into my office to-day who had never been taught forceps, nor version, nor manikin work while in college, and has always been so honest that he has invariably called on a neighboring friendly consultant to deliver his difficult cases for him. He has now resolved to take a clinical course in obstetrics to prepare himself for his work.

Every student when he graduates and goes out into the world on his own resources realizes his handicap of lack of accurate diagnosis. He does not need a vast demonstration of heroic surgery; he will call a competent surgical expert for that part of his work. What he needs is diagnostic ability in internal medicine and surgery and skill to manage his obstetric patients so that his care of them will not be a reproach to him, nor to the school from which he has graduated.

GEORGE CLARK MOSHER, Kansas City, Mo.

Contagion and Consistency—A Rejoinder

To the Editor:—I note in THE JOURNAL, July 24, a communication from Dr. Emil Roy on "Contagion and Consistency." It is not improper to remark that the writer would do well to show in his statements some consistency with the real facts which are being brought out in investigations of infectious diseases. Such statements as: "Clothing and other fomites are great carriers of infection," and "infected clothing that has been unused for years has been the cause of epidemics," are admitted by authorities, well able to judge, to be made entirely without sufficient grounds, and there is yet to be recorded a single satisfactory substantiated instance that shows such to be the case.

As stated recently by Dr. A. H. Doty, health officer of the Port of New York, in the *American Journal of Medical Sciences*, the old custom of attributing every obscure source of infection to fomites, has too long been in use by the medical profession and has proved a hindrance to the real solution of the problem of infectious diseases.

The work of Kayser, Drigalski, Lentz and Conradi on typhoid; that of von Lingelsheim, Osterman, Flügge, Kolle and Wassermann, Elser and Huntoon and others in cerebrospinal meningitis, and the investigations of the various boards of health, notably Massachusetts and New York, on scarlet fever and diphtheria, indicate in no uncertain manner that the time is passed when but a minor number of infections can be promiscuously laid to clothing, books and what not, and that the greater portion of infections with so-called contagious diseases, can be definitely traced to direct contact of uninfected persons with individuals who either in health or ill with the disease, are harboring and excreting the specific organism.

In place of Dr. Roy's statement that "we understand the germ theory and how diseases are disseminated," it would be well to substitute: "We are beginning to understand the real manner in which diseases are disseminated," and that the theory of fomites in this connection is largely exhausted.

H. S. HAMMOND, M.D., Trenton, N. J.

"Data is"—A Protest

To the Editor:—Correct—not to say elegant—English is most desirable in medical literature as in all other publications. The erroneous use of "data" with a verb in the singular is becoming deplorably frequent. I have seen it lately in no fewer than four instances: in a recent number of THE JOURNAL, by a well-known surgeon; in a medical paper, by a promising young investigator; in a scientific report on the Panama Canal; and in an editorial in one of our best weeklies.

"Data" is of course the plural of "datum," as "strata" is the plural of "stratum." Its use with a verb in the singular, as acknowledged by the editor of the paper alluded to, is due to haste and carelessness. It can hardly be attributed to ignorance in any of the four instances cited. But it ought never to occur.

Is not this one of the cases in which the editor or the proofreader should correct so evident a slip and not allow the error to become habitual? "Where am I at," from being a joke, is in danger of becoming a common locution. The same possibility exists in "data is" unless checked at the beginning.

W. W. KEEN, Philadelphia.

Miscellany

Epidemic of Urticarioid Dermatitis from a Mite in Straw Mattresses

In a preliminary report to the Surgeon-General of the Public Health and Marine-Hospital Service, Drs. Joseph Goldberger and Jay F. Schamberg call attention (Public Health Reports, July 9, 1909, page 973) to an epidemic of urticarioid dermatitis due to a small mite (*Pediculoides ventricosus*) in the straw of mattresses. The epidemic had prevailed in Philadelphia and vicinity since the early part of May, 1909, though the authors state that the disease probably occurs more or less in various parts of the United States. This eruptive disease was first noted among a crew on a private yacht docked in the Delaware river; at about the same time more cases appeared among the crew of other boats and also various private residences and boarding houses in Philadelphia and vicinity.

In nearly every case it was determined that the patients had either recently slept on new straw mattresses or had freely handled the same. The various mattresses had come from one of four different manufacturers, all of whom obtained their straw from the same source. In order to establish experimentally the etiologic rôle of the straw, one of the authors exposed a bare arm and shoulder for one hour between two straw mattresses. Sixteen hours later the characteristic itching eruption occurred. Later three people voluntarily slept on some of the mattresses for one night and each developed the eruption. Untreated siftings from the straw when applied to the axillæ produced the eruption; siftings that had been exposed under a bell jar for one hour to the fumes of chloroform, when similarly applied, proved innocuous. Careful scrutiny of some of the fresh siftings disclosed the presence of a very small mite which, when applied to the axilla, produced the characteristic eruption. The mite was identified by Mr. Nathan Banks of the United States Bureau of Entomology as being "very close to, if not identical with, *Pediculoides ventricosus.*"

The eruption consists of wheals, nearly all of which are surmounted by a central vesicle which becomes pustular. The primary efflorescences may be erythemato-urticarial spots or papulo-urticarial lesions, varying in size from that of a lentil seed to that of a finger nail, and are rounded, oval or irregular in shape. The lesions but rarely show the pinkish-white anemic area of ordinary "hives," being usually of a warm rose color. The eruption extends over the neck, chest, abdomen and back, and in a lesser degree over the arms and thighs. Scattered lesions may appear on the face, but the hands and feet are usually free. Some patients exhibit systemic symptoms; malaise, anorexia and sometimes an elevation of temperature of from 99 F. to 102 F. There may be a moderate enlargement of the subcutaneous lymph glands and a transient albuminuria. The condition is likely to be confounded with urticaria, chickenpox or scabies.

Prophylaxis consists in exposing the mattress to the fumes of sulphur or formaldehyd in a vacuum chamber. For the relief of itching and the cure of the cutaneous condition, the authors recommend the following:

℞.	gm.		
Betanaphtolis	2		gr. xxx
Sulphuris præcipitati	4	or	ʒi
Adipis benzoinati	31		℥i

Accidents in Obstetric Operations and Their Forensic Aspect.—O. von Franqué calls attention to the excellent provision adopted in Austria in 1903 for all charges of malpractice against physicians. When a suit is to be brought against a physician for alleged malpractice, the prosecuting attorney must first obtain a certificate on the affair from the faculty of the university, signed by at least nine members of the faculty after two or three have studied the matter thoroughly and made out the certificate. If this certificate testifies that there has been no criminal malpractice, the affair ends there so far as the prosecuting attorney is concerned, and it does not become public, although the injured parties may still bring a civil suit, but they generally realize the hopelessness of their case and desist. By this means physicians are protected against heedless bringing of suits which tarnish their professional reputation even if terminating in acquittal. Franqué contributes an article on the subject to the *Sammlung klinischer Vorträge*, No. 524, reviewing a number of experiences in this line to which he had to testify while in the medical faculty at Prague. In one case the obstetrician mistook a breech for a frontal presentation in a difficult labor and attempted to perforate, supposing the child was dead. It proved to be alive and was born with a wound in the thigh and transient peroneus paralysis, but no other injury either to mother or child. The parents sent a lawyer to the physician to demand damages, but he threatened a counter suit for blackmail and the matter was dropped. In another case the obstetrician drew out the entire uterus and adnexa, his hand entering through the posterior vault of the vagina and a long rent in the uterus, when he supposed he was merely releasing the placenta. In another case of laceration of the uterus the obstetrician left the patient before delivery of the placenta, saying that nothing more could be done at present. In a fourth case, a vesicovaginal fistula following a forceps delivery was ascribed to the physician's carelessness. The faculty certificates in all these cases stated the grounds why the physician was not responsible for the fatality. The public never learned of the affair in some cases. Franqué urges all obstetricians to make an unfailing practice of writing out in detail the next day the complete history of the case when an accident of this kind has occurred. Such a candid, objective history, made out before there is any question of legal proceedings, has great influence on the authorities and experts, and will often turn the scale against any assumption of negligence. The favorable outcome in the first of the above cases was evidently due to this history of the case written spontaneously and objectively while the data were fresh.

Problem of the State in the Care of the Insane.—The task which a state must face in the care of its insane is outlined by Adolph Meyer in the *American Journal of Insanity*, April, 1909, follows: 1. The care of the insane is to be organized so that care is given at as early a date as possible, that is, before the time when commitment is now thought necessary. 2. A system of notification of a mental health board is to make organized activity possible; and adequate provisions with hospital nurses, not policemen and jails, must be available, pending the transfer to the specially organized hospitals. 3. The special hospital must have adequate treatment divisions where it is possible to become thoroughly acquainted with all the facts about the patient before his transfer into the ordinary observation wards for a more lasting stay. 4. Even in the wards for the supposedly more chronic cases, standards must be maintained that provide for the 25 per cent. or more of recoverable cases in which illness lasts more than a year. 5. Adequate provisions must be made to become thoroughly acquainted with the outside conditions under which the disorder developed, and with the possibilities of an adjustment before the patient returns, so that such help or guidance as may be advantageous to the patient and to his friends on his return from the hospital may be extended. 6. General organizations of work must be carried out in the locality, according to its needs, among the various types of the community, not only with regard to checking alcoholism and the spread of syphilis, but also with regard to hygienic methods of living generally; emphasis must be laid on keeping the minds balanced with a due share of recreation and rest, and satisfaction with the returns of every-day toil.

Ocular Manifestations of Hysteria.—C. E. Finlay of Havana contributes an article to the *Revista de Med. y Cirugia*, May 10, protesting against the prevalent disregard of the ocular manifestations of hysteria. It is probably, he says, the reaction from the excessive importance ascribed to the ocular manifestations by the clinicians of the Paris Salpêtrière school. He states that he has encountered six typical cases among 13,000 patients, and describes these six cases in detail. In none were there any pupil phenomena. The first patient was a man of 33 with amblyopia without ocular lesions, concentric contraction of the visual field and incomplete color blindness. He had had a similar attack of amblyopia a year before. The functioning of the eye soon returned to normal under a course of tonics, except that the contracted visual field and dyschromatopsia persisted for several months. The second patient was a boy of 12 presenting concentric contraction of the visual field and other signs of hysterotraumatism following a severe blow in the left temple. The third patient was a young physician with diplopia; powerful iodid treatment had been pushed on the assumption of possible syphilis. Paralysis of both internal recti seemed the only diagnosis until the concentric contraction of the visual field and partial color blindness revealed the hysteric origin of the trouble. The patient refused to accept this diagnosis but suspended treatment and recovery soon followed. Another patient was a young man with one useless eye. The other eye was normal except for hypermetropia, but it was hit with a snowball and he had to stay in his room for two months, after which vision in this eye was much reduced. The visual field was concentrically contracted and there was partial color blindness, but the amblyopia rapidly subsided under rest, bromids and tonics. His two other patients were a woman of 27 and a girl of 11, both with the bilateral concentrically contracted visual field; the girl presented also monocular polyopia and nystagmus.

Maydl's Operation for Exstrophy of the Bladder.—J. Jellinek of Brünn, Austria, reviews the experiences of the last fifteen years with Maydl's operation for exstrophy of the bladder. He tabulates the details of 177 cases as reported by 92 different surgeons—including a number of Americans—and answers the objections that have been made to the Maydl technic. None of them has any weight, he shows, except the possibility of ascending infection, and this is counterbalanced by the superior functional results, the high mortality of the non-operated from pyelonephritis or malignant tumors which seem to display a predilection for the exposed bladder mucosa, and by the large number of permanently cured patients. The records show 17 cured for over 2 years; 13 for over 3; 7 for over 4; 25 for from 5 to 9 years, and 1 each for 10, 11 and 12 years. The age at which the operation is performed is an important factor in the outcome; the mortality under 5 was 41 per cent.; between 6 and 10, 18 per cent.; between 11 and 20, 32:5 per cent.; between 21 and 25, 50 per cent., and above this age, 72 per cent. The mortality from pyelonephritis also increased with age, from 3 and 9 per cent. under 15 to 54 per cent. after the age of 25. Sooner or later, 25 per cent. of the patients who had been operated on succumbed to this. Careful selection of the cases for operative treatment and improved technic in means to keep the urine and stools separate will make the outcome still better. The illustrated monograph appeared originally in the *Casopis lekaru ceskych* not long ago. The various other methods for treatment of exstrophy of the bladder and the ultimate outcome are described and compared with the Maydl "derivation" technic. Only four of all the patients operated on were women, and none of the women operated on for exstrophy of the bladder conceived later, although in one case the Maydl operation had been done for a tuberculous bladder affection and the girl married and bore a child later. There are 10 cases on record, he says, of pregnancy in women with exstrophy of the bladder, unoperated; as a rule, there are usually other malformations which interfere with conception.

Changes in the Duodenal Glands of the Rabbit After Ligation of the Duct of Wirsung.—A Marassini, in his reported experiments (*Arch. ital. de biol.*, 1909, xlix, 1) paid particular attention to those glands of the normal duodenum which bear a resemblance to the acini of the pancreas and which are known as the pancreas duodenalis. Marassini observed that within fifteen days after ligature of the pancreatic duct, there appeared in the submucosa of the duodenum a definite layer of tubuli. These tubuli in the main were composed of cells with intensive staining protoplasm. The remaining tubuli with bright transparent elements were now comparatively few in number. In the normal animal the tubuli with clear transparent cells greatly preponderate over the tubuli with intensively staining cells. After ligation of the duct, however, the proportion of the two kinds of tubuli are just reversed. With high magnification the intensively staining pancreas-like tubuli are seen to be made up of pear-shaped cells which bear a remarkable resemblance to the cells of the pancreatic acini. The similarity is further made evident by the presence in the cells of the deeply staining tubuli of a great many fuchsin-staining granules. These granules are homologous to the zymogen granules (i. e., granules from which the various ferments of the pancreatic juice are directly formed) of the acinous cells of the pancreas, and in the experimental animals their number was very greatly increased in the cells of the pancreas duodenalis. It is believed that these tubules with deeply staining cells represent structures of a nature similar to that of the acini of the normal pancreas and that after ligation of the pancreatic duct they greatly increase in number and take over the function of secreting pancreatic ferments to such an extent that they entirely compensate for the loss of the pancreatic secretion by ligation.

Orthodontia.—The opinion that a revolution in dentistry is taking place with the development of orthodontia is expresssed by Dr. Richard Cole Newton in the *Popular Science Monthly*, July, 1909. He describes the results obtained by straightening teeth and securing their proper arrangement in the jaw as adding greatly to human beauty, health and efficiency. The position of the teeth is held to determine the shape of the jaws, so that a jaw ordinarily held to be indicative of degeneracy assumes a form characteristic of the highest human type if the teeth are properly manipulated at the proper time. The opinion that man is gradually evolving into a toothless animal is given little support by results secured by these modern artists of the human face. The evidence presented by Dr. Newton, especially that in pictorial form is very convincing and serves to emphasize the fact that dentistry is a specialty of medicine with which every physician should be more familiar. The family physician should recognize the importance of the preservation of the teeth and should extract one only for very good reasons. The relations of the teeth to good digestion are properly emphasized by Dr. Newton, but it may be well to suggest that as the majority of digestive complaints are of functional and even of psychic character it is not safe to conclude without sufficient investigation that a particular case of gastric trouble owes its origin to poor teeth. On the other hand, there is reason for the view that both the poor teeth and the dyspepsia depend on an underlying fault of the nervous system. This view is supported by the frequent presence of the changes in the skeleton which constitute the signs of Stiller's asthenia congenita. Orthodontia may restore the teeth and jaws to proper form, but it is hardly likely to remove the congenital degenerative tendencies which form the basis of modern neurasthenia.

The Pressor Principles of Placental Extracts.—An examination of the alcoholic extracts of the human placenta was undertaken by Otto Rosenheim (*Jour. Physiol.*, 1909, xxxviii, 339) with the view of isolating the active principles observed by Dixon and Taylor (*Brit. Med. Jour.*, 1907, ii, 1150) to produce on intravenous injection a rise of blood pressure and a contraction of the pregnant uterus, and to establish the identity or otherwise of the active principles of placental extract with those of adrenalin or similar substances. By none of the well-known methods used in isolating adrenalin was a product obtained which gave any of the reactions of adrenalin. Furthermore, when care was taken to prevent bacterial putrefaction, the pressor principles were absent from extracts of placentaa prepared by any one of half a dozen methods, including the method of Dixon and Taylor. Under all conditions which freely permit autolytic processes to go on, with precautions against bacterial infection, the active principles are not produced. The method of Dixon and Taylor permits of bacterial infection in which case the active pressor principles are present. Rosenheim concludes: "Fresh human placenta does not contain any pressor principle. The pressor principles of placental extracts, prepared according to Dixon and Taylor, are products of initial putrefaction. The autolytic enzymes of the placenta, without the help of micro-organisms, are unable to produce pressor substances. Several pressor bases were isolated from putrefying placenta, the most active of which was identified as p-hydroxyphenylethylamin, while the identity of another with isoamylamin is most probable. These are identical with those found by Barger and Walpole in putrid meat."

The Ideal Fly Killer.—Now that so much is being said about the necessity of extirpating house flies, a communication to *Nature* of May 13 is of interest. Dr. Alexander Hill, writing from Mentone, says that the most efficient fly destroyer with which he is acquainted is a dilute solution of formaldehyd. If two teaspoonfuls of formalin (40 per cent. formaldehyd) be added to a soup-plate filled with water, the flies go to it to drink, especially in the early afternoon. Some die in the water, others fall in the neighborhood of the plate, and others elsewhere in the room. With a single plate of the solution on the kitchen table, he says, hundreds of dead flies are daily swept up from the floor. He is writing from the south of France where screening does not seem to be so universal, or flies are especially abundant. It is somewhat strange, as he says, that so small a dose should prove fatal when taken into the fly's alimentary canal. To free a room of flies by vaporizing formalin the air would have to be rendered irrespirable by a human being. Formaldehyd in very dilute solution has no particular odor and he gives this fact of its deadliness to flies as an evidence that their olfactory sense must be very similar in this respect to our own. The solution neither attracts nor repels flies, for a similar plate containing only pure water will be equally visited by them. The formalin may be added to a dish of water containing flowers, if equally accessible to the flies, with the same result as far as fly killing is concerned; the plants are not affected other than as slightly in regard to their tints by the formalin. Though not specially intended as such the communication is very apropos as a sanitary item at the present time.

Tabes and Pregnancy.—MM. H. Dufour and Cottinot report (*Bull. et mém. Soc. méd. d. hôp. de Paris*, Feb. 5, 1909, p. 211) the case of a woman, aged 29, secundipara, and three months pregnant, who had never shown any signs of tabes (unless we consider excessive vomiting during her first pregnancy and on one other occasion to be of that nature), but who was suddenly taken with uncontrollable emesis. Examination revealed a number of tabetic symptoms, occurring all at once at this time. Previously the patient had considered herself in perfect health and had done her work. She was temperate and there had been no history or signs that could be referred to syphilitic infection. Neither she nor her husband could give any history of the pre-existence of the inco-ordination or other tabetic symptoms. One fact, however, that was learned is significant. In January, 1908, she had severe attacks of vomiting and a laparotomy was performed in the left iliac fossa, apparently on a diagnosis of bowel obstruction, which was not found and the wound was closed and she recovered. It is more than probable that this was a simple gastric crisis of tabes, but it suggests an important practical point in the diagnosis. The excessive reaction of pregnancy on tabes is, however, the chief thing of interest in the case. Another similar case is briefly mentioned and reference is made to still others reported by Heitz and others in which the symptoms of tabes were aggravated by pregnancy. Mercurial injections brought the first patient reported by the authors to term.

Fixation Abscesses in Treatment of Lead Poisoning.—J. Carles of Bordeaux has been conducting experimental research, the results being confirmed by clinical experience, which reaffirms the way in which metallic salts circulating in the organism are attracted to an inflammatory focus and are eliminated in the pus. In some of the dogs injected with turpentine after chronic lead poisoning to cause the "fixation abscess," the pus contained a larger proportion of lead than could be found in equal weights of brain or liver tissue. The turpentine was not injected until after the lead had been deposited in the viscera, the experiences showing that the leucocytes were able to recapture the lead and transport it to the fixation abscess; the kidneys and blood contained only traces, while 25 gm. of pus contained 0.003 gm. of lead sulphid. In the two clinical cases related in his communication in the *Bull. Gén. de Thérapeutique*, Feb. 8, 1909, the pus did not contain a very large proportion of lead, but every little may help in the serious cases, he says.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

TREATMENT OF LEAD POISONING

To the Editor:—I wish to know the best treatment for plumbism, such as is found around a lead smelter and in lead mines; especially for a patient who has gone from 3 to 6 days without a bowel movement. I have a smelter company's practice, and have from 10 to 100 cases a month. I have never been able to find any work on it in English.

J. M. SPAULDING, M.D., Silver City, Utah.

ANSWER.—The treatment of lead poisoning includes the prevention of further poisoning by removal of the cause; especial care should be taken to secure cleanliness and especially to prevent eating with soiled hands. The elimination of the poison is favored by copious ingestion of water, warm baths, and the administration of potassium iodid in doses of 0.3 gm. (5 grains) three times a day.

The symptoms must be treated as they arise. Constipation should be relieved by the milder laxatives, such as magnesium sulphate, senna, etc., if possible. Sometimes more active cathartics must be given. For paralysis full doses of strychnin simultaneously with large doses of potassium iodid must be given. The faradic current is useful in paralysis of the extremities. Colic should be relieved by morphin hypodermically. This sometimes relieves the constipation at the same time.

In the report of the Committee on Social Betterment of the President's Homes Commission, Dr. William J. Manning's article on "Plumbism" is reproduced. In this article Dr. Manning says: "In acute cases of lead poisoning the treatment consists in the administration of alkaline carbonates, soap, soluble sulphates, sodium chlorid, etc., washing out the stomach with large drafts of water, etc. Alum has been given, and at one time was considered almost a specific. Sweet oil and castor oil will be found useful. Milk should be taken in large quantities. The idea is first to combat the symptoms and then to eliminate the lead. Opium can be given for pain. Warm sulphureted baths are very beneficial. They can be made by dissolving 4 ounces of potassium sulphid in 30 gallons of water in a wooden tub. These baths discolor the skin from the formation of lead sulphid, and should be repeated every few days until this effect ceases. During each bath the patient should be well washed with soap and water to remove discoloration."

In Great Britain dangerous trades are regulated by special provisions in the factory and workshop act. Under the head of "Lead Smelting Works," the following duties of employers are prescribed:

"*Duties of Occupiers:* (1) They shall provide respirators and overall suits for the use of all persons employed in cleaning the flues, and take means to see that the same are used. (2) They shall arrange that no person be allowed to remain at work more than two hours at a time in a flue—a rest of half an hour before re-entering will be deemed sufficient. (3) They shall provide sufficient bath accommodation for all persons employed in cleaning the flues, and every one so employed shall take a bath before leaving the works. (4) They shall provide washing conveniences, with sufficient supply of hot and cold water, soap, nail-brushes and towels."

To insure the carrying out of these rules, the workmen are held liable should they fail to comply with them, a fine not exceeding two pounds ($10) being imposed. Since the enforcement of these preventive measures there has been in England a most marked reduction in the morbidity and mortality from lead poisoning.

A work that might be of interest to our correspondent is "Lead Poisoning," by Thomas Oliver, published by Young J. Pentland, Edinburgh.

SHAMPOO FORMULAS

To the Editor:—Will you kindly tell me what is a good formula for a shampoo, and what other soft soap besides green soap is on the market? How are these liquid soaps made? Are they merely boiled, dilute green or soft soap?

ENQUIRER, Chicago.

ANSWER.—While many proprietary soft soaps and prepared shampoos are for sale, none is superior to the official soft soap (Sapo Mollis U. S. P.) in convenience or effectiveness. This may be found stronger than is desired and will be too harsh on the hair in some cases. A good castile soap may be made soft by being cut up and boiled with a little water. For convenience a solution of soft soap in alcohol to which a little oil of bergamot or other essential oil has been added is often used. The National centric contraction of the visual field and incomplete color blindness. He had had a similar attack of amblyopia a year before. The functioning of the eye soon returned to normal under a course of tonics, except that the contracted visual field and dyschromatopsia persisted for several months. The second patient was a boy of 12 presenting concentric contraction of the visual field and other signs of hysterotraumatism following a severe blow in the left temple. The third patient was a young physician with diplopia; powerful iodid treatment had been pushed on the assumption of possible syphilis. Paralysis of both internal recti seemed the only diagnosis until the concentric contraction of the visual field and partial color blindness revealed the hysteric origin of the trouble. The patient refused to accept this diagnosis but suspended treatment and recovery soon followed. Another patient was a young man with one useless eye. The other eye was normal except for hypermetropia, but it was hit with a snowball and he had to stay in his room for two months, after which vision in this eye was much reduced. The visual field was concentrically contracted and there was partial color blindness, but the amblyopia rapidly subsided under rest, bromids and tonics. His two other patients were a woman of 27 and a girl of 11, both with the bilateral concentrically contracted visual field; the girl presented also monocular polyopia and nystagmus.

Maydl's Operation for Exstrophy of the Bladder.—J. Jellinek of Brünn, Austria, reviews the experiences of the last fifteen years with Maydl's operation for exstrophy of the bladder. He tabulates the details of 177 cases as reported by 92 different surgeons—including a number of Americans—and answers the objections that have been made to the Maydl technic. None of them has any weight, he shows, except the possibility of ascending infection, and this is counterbalanced by the superior functional results, the high mortality of the non-operated from pyelonephritis or malignant tumors which seem to display a predilection for the exposed bladder mucosa, and by the large number of permanently cured patients. The records show 17 cured for over 2 years; 13 for over 3; 7 for over 4; 25 for from 5 to 9 years, and 1 each for 10, 11 and 12 years. The age at which the operation is performed is an important factor in the outcome; the mortality under 5 was 41 per cent.; between 6 and 10, 18 per cent.; between 11 and 20, 32:5 per cent.; between 21 and 25, 50 per cent., and above this age, 72 per cent. The mortality from pyelonephritis also increased with age, from 3 and 9 per cent. under 15 to 54 per cent. after the age of 25. Sooner or later, 25 per cent. of the patients who had been operated on succumbed to this. Careful selection of the cases for operative treatment and improved technic in means to keep the urine and stools separate will make the outcome still better. The illustrated monograph appeared originally in the *Casopis lekaru ceskych* not long ago. The various other methods for treatment of exstrophy of the bladder and the ultimate outcome are described and compared with the Maydl "derivation" technic. Only four of all the patients operated on were women, and none of the women operated on for exstrophy of the bladder conceived later, although in one case the Maydl operation had been done for a tuberculous bladder affection and the girl married and bore a child later. There are 10 cases on record, he says, of pregnancy in women with exstrophy of the bladder, unoperated; as a rule, there are usually other malformations which interfere with conception.

Changes in the Duodenal Glands of the Rabbit After Ligation of the Duct of Wirsung.—A Marassini, in his reported experiments (*Arch. ital. de biol.*, 1909, xlix, 1) paid particular attention to those glands of the normal duodenum which bear a resemblance to the acini of the pancreas and which are known as the pancreas duodenalis. Marassini observed that within fifteen days after ligature of the pancreatic duct, there appeared in the submucosa of the duodenum a definite layer of tubuli. These tubuli in the main were composed of cells with intensive staining protoplasm. The remaining tubuli with bright transparent elements were now comparatively few in number. In the normal animal the tubuli with clear transparent cells greatly preponderate over the tubuli with intensively staining cells. After ligation of the duct, however, the proportion of the two kinds of tubuli are just reversed. With high magnification the intensively staining pancreas-like tubuli are seen to be made up of pear-shaped cells which bear a remarkable resemblance to the cells of the pancreatic acini. The similarity is further made evident by the presence in the cells of the deeply staining tubuli of a great many fuchsin-staining granules. These granules are homologous to the zymogen granules (i. e., granules from which the various ferments of the pancreatic juice are directly formed) of the acinous cells of the pancreas, and in the experimental animals their number was very greatly increased in the cells of the pancreas duodenalis. It is believed that these tubules with deeply staining cells represent structures of a nature similar to that of the acini of the normal pancreas and that after ligation of the pancreatic duct they greatly increase in number and take over the function of secreting pancreatic ferments to such an extent that they entirely compensate for the loss of the pancreatic secretion by ligation.

Orthodontia.—The opinion that a revolution in dentistry is taking place with the development of orthodontia is expresssed by Dr. Richard Cole Newton in the *Popular Science Monthly*, July, 1909. He describes the results obtained by straightening teeth and securing their proper arrangement in the jaw as adding greatly to human beauty, health and efficiency. The position of the teeth is held to determine the shape of the jaws, so that a jaw ordinarily held to be indicative of degeneracy assumes a form characteristic of the highest human type if the teeth are properly manipulated at the proper time. The opinion that man is gradually evolving into a toothless animal is given little support by results secured by these modern artists of the human face. The evidence presented by Dr. Newton, especially that in pictorial form is very convincing and serves to emphasize the fact that dentistry is a specialty of medicine with which every physician should be more familiar. The family physician should recognize the importance of the preservation of the teeth and should extract one only for very good reasons. The relations of the teeth to good digestion are properly emphasized by Dr. Newton, but it may be well to suggest that as the majority of digestive complaints are of functional and even of psychic character it is not safe to conclude without sufficient investigation that a particular case of gastric trouble owes its origin to poor teeth. On the other hand, there is reason for the view that both the poor teeth and the dyspepsia depend on an underlying fault of the nervous system. This view is supported by the frequent presence of the changes in the skeleton which constitute the signs of Stiller's asthenia congenita. Orthodontia may restore the teeth and jaws to proper form, but it is hardly likely to remove the congenital degenerative tendencies which form the basis of modern neurasthenia.

The Pressor Principles of Placental Extracts.—An examination of the alcoholic extracts of the human placenta was undertaken by Otto Rosenheim (*Jour. Physiol.*, 1909, xxxviii, 339) with the view of isolating the active principles observed by Dixon and Taylor (*Brit. Med. Jour.*, 1907, ii, 1150) to produce on intravenous injection a rise of blood pressure and a contraction of the pregnant uterus, and to establish the identity or otherwise of the active principles of placental extract with those of adrenalin or similar substances. By none of the well-known methods used in isolating adrenalin was a product obtained which gave any of the reactions of adrenalin. Furthermore, when care was taken to prevent bacterial putrefaction, the pressor principles were absent from extracts of placentaa prepared by any one of half a dozen methods, including the method of Dixon and Taylor. Under all conditions which freely permit autolytic processes to go on, with precautions against bacterial infection, the active principles are not produced. The method of Dixon and Taylor permits of bacterial infection in which case the active pressor principles are present. Rosenheim concludes: "Fresh human placenta does not contain any pressor principle. The pressor principles of placental extracts, prepared according to Dixon and Taylor, are products of initial putrefaction. The autolytic enzymes of the placenta, without the help of micro-organisms, are unable to produce pressor substances. Several pressor bases were isolated from putrefying placenta, the most active of which was identified as p-hydroxyphenylethylamin, while the identity of another with isoamylamin is most probable. These are identical with those found by Barger and Walpole in putrid meat."

The Ideal Fly Killer.—Now that so much is being said about the necessity of extirpating house flies, a communication to *Nature* of May 13 is of interest. Dr. Alexander Hill, writing from Mentone, says that the most efficient fly destroyer with which he is acquainted is a dilute solution of formaldehyd. If two teaspoonfuls of formalin (40 per cent. formaldehyd) be added to a soup-plate filled with water, the flies go to it to drink, especially in the early afternoon. Some die in the water, others fall in the neighborhood of the plate, and others elsewhere in the room. With a single plate of the solution on the kitchen table, he says, hundreds of dead flies are daily swept up from the floor. He is writing from the south of France where screening does not seem to be so universal, or flies are especially abundant. It is somewhat strange, as he says, that so small a dose should prove fatal when taken into the fly's alimentary canal. To free a room of flies by vaporizing formalin the air would have to be rendered irrespirable by a human being. Formaldehyd in very dilute solution has no particular odor and he gives this fact of its deadliness to flies as an evidence that their olfactory sense must be very similar in this respect to our own. The solution neither attracts nor repels flies, for a similar plate containing only pure water will be equally visited by them. The formalin may be added to a dish of water containing flowers, if equally accessible to the flies, with the same result as far as fly killing is concerned; the plants are not affected other than as slightly in regard to their tints by the formalin. Though not specially intended as such the communication is very apropos as a sanitary item at the present time.

Tabes and Pregnancy.—MM. H. Dufour and Cottinot report (*Bull. et mém. Soc. méd. d. hôp. de Paris*, Feb. 5, 1909, p. 211) the case of a woman, aged 29, secundipara, and three months pregnant, who had never shown any signs of tabes (unless we consider excessive vomiting during her first pregnancy and on one other occasion to be of that nature), but who was suddenly taken with uncontrollable emesis. Examination revealed a number of tabetic symptoms, occurring all at once at this time. Previously the patient had considered herself in perfect health and had done her work. She was temperate and there had been no history or signs that could be referred to syphilitic infection. Neither she nor her husband could give any history of the pre-existence of the inco-ordination or other tabetic symptoms. One fact, however, that was learned is significant. In January, 1908, she had severe attacks of vomiting and a laparotomy was performed in the left iliac fossa, apparently on a diagnosis of bowel obstruction, which was not found and the wound was closed and she recovered. It is more than probable that this was a simple gastric crisis of tabes, but it suggests an important practical point in the diagnosis. The excessive reaction of pregnancy on tabes is, however, the chief thing of interest in the case. Another similar case is briefly mentioned and reference is made to still others reported by Heitz and others in which the symptoms of tabes were aggravated by pregnancy. TREATMENT OF LEAD POISONING

To the Editor:—I wish to know the best treatment for plumbism, such as is found around a lead smelter and in lead mines; especially for a patient who has gone from 3 to 6 days without a bowel movement. I have a smelter company's practice, and have from 10 to 100 cases a month. I have never been able to find any work on it in English.

J. M. SPAULDING, M.D., Silver City, Utah.

ANSWER.—The treatment of lead poisoning includes the prevention of further poisoning by removal of the cause; especial care should be taken to secure cleanliness and especially to prevent eating with soiled hands. The elimination of the poison is favored by copious ingestion of water, warm baths, and the administration of potassium iodid in doses of 0.3 gm. (5 grains) three times a day.

The symptoms must be treated as they arise. *Constipation* should be relieved by the milder laxatives, such as magnesium sulphate, senna, etc., if possible. Sometimes more active cathartics must be given. For paralysis full doses of strychnin simultaneously with large doses of potassium iodid must be given. The faradic current is useful in paralysis of the extremities. Colic should be relieved by morphin hypodermically. This sometimes relieves the constipation at the same time.

In the report of the Committee on Social Betterment of the President's Homes Commission, Dr. William J. Manning's article on "Plumbism" is reproduced. In this article Dr. *Manning says:* "In acute cases of lead poisoning the treatment consists in the administration of alkaline carbonates, soap, soluble sulphates, sodium chlorid, etc., washing out the stomach with large drafts of water, etc. Alum has been given, and at one time was considered almost a specific. Sweet oil and castor oil will be found useful. Milk should be taken in large quantities. The idea is first to combat the symptoms and then to eliminate the lead. *Opium can* be given for pain. Warm sulphureted baths are very beneficial. They can be made by dissolving 4 ounces of potassium sulphid in 30 gallons of water in a wooden tub. These baths discolor the skin from the formation of lead sulphid, and should be repeated every few days until this effect ceases. During each bath the patient should be well washed with soap and water to remove discolor*ation.*"

In Great Britain dangerous trades are regulated by special provisions in the factory and workshop act. Under the head of "Lead Smelting Works," the following duties of employers are prescribed:

"*Duties of Occupiers:* (1) They shall provide respirators and overall suits for the use of all persons employed in cleaning the flues, and take means to see that the same are used. (2) They shall arrange that no person be allowed to remain at work more than two hours at a time in a flue—a rest of half an hour before re-entering will be deemed sufficient. (3) They shall provide sufficient bath accommodation for all persons employed in cleaning the flues, and every one so employed shall take a bath before leaving the works. (4) They shall provide washing conveniences, with sufficient supply of hot and cold water, soap, nail-brushes and towels."

To insure the carrying out of these rules, the workmen are held liable should they fail to comply with them, a fine not exceeding two pounds ($10) being imposed. Since the enforcement of these preventive measures there has been in England a most marked reduction in the morbidity and mortality from lead poisoning.

A work that might be of interest to our correspondent is "Lead Poisoning," by Thomas Oliver, published by Young J. Pentland, Edinburgh.

SHAMPOO FORMULAS

To the Editor:—Will you kindly tell me what is a good formula for a shampoo, and what other soft soap besides green soap is on the market? How are these liquid soaps made? Are they merely boiled, dilute green or soft soap?

ENQUIRER, Chicago.

ANSWER.—While many proprietary soft soaps and prepared shampoos are for sale, none is superior to the official soft soap (Sapo Mollis U. S. P.) in convenience or effectiveness. This may be found stronger than is desired and will be too harsh on the hair in some cases. A good castile soap may be made soft by being cut up and boiled with a little water. For convenience a solution of soft soap in alcohol to which a little oil of bergamot or other essential oil has been added is often used. The National

Formulary contains a Compound Tincture of Green Soap, which consists of soft soap 150 gm., oil of cade 20 c.c. and alcohol enough to make 1,000 c.c. The official soft soap is made by treating linseed oil with an excess of potassium hydroxid and small quantities of alcohol and water are added to aid in the saponification. The various preparations of liquid soap which are found on the market differ chiefly from the official soft soap in that other oils than linseed oil may have been used in their preparation and also in the varying alcohol and water content.

The following formulas of liquid egg shampoos were given in the Therapeutic Department of The Journal March 14, 1908; they are both from the *Druggists Circular:*

Soft soap	2 ounces
Whites of	4 eggs
Potassium carbonate	1 ounce
Tar water	1 pint
Glycerin	2 ounces
Orange flower water, enough to make	2 ounces

Beat the whites of the eggs into a froth while gradually adding the tar water. Dissolve the soap in a mixture of glycerin and six ounces of orange flower water. Mix the two solutions and make up to two pints with orange flower water.

Also:

Transparent soap	4 ounces
Glycerin	2 ounces
Whites of	3 eggs
Tincture of green soap	1 ounce.
Oil of rosemary	45 minims
Oil of rose geranium	30 minims
Water, enough to make	2 pints

Melt the soap in twelve ounces of water, add the glycerin and stir until cool; then add the green soap and the oils. Mix the whites of the eggs with eight ounces of water and stir into the soap mixture. Shake well, let stand for twenty-four hours, and strain through flannel.

BUTTERMILK THERAPY AND MILKS AS FOOD

To the Editor:—In your excellent editorial on buttermilk therapy occurs the sentence, "it is not likely that any one would live on such a diet except for experimental purposes." Now so far as I know every pastoral people compelled to use milk largely as a diet does ferment its milk by some complicated process. This is so unlikely to happen that it demands consideration. I would be glad to know if there is any exception to it, or if you can suggest any explanation other than the evolutionary one, i. e., that every race that has tried to live on sweet milk has died out. Clinical experience has inclined me to the theory that intestinal toxemia is more likely to occur from sweet milk than from sour. I make my sour milk, by the way, with hydrochloric acid rather than with a ferment. I am of course aware of the unreliability of clinical impression and agree that the theory should be tested in every way before it is stated as a fact. But the extensive use of ferments among semicivilized people seems to me an item of evidence which should be considered.

John W. Boyce, M.D., Pittsburg.

Answer.—To the great majority of adults, sweet milk becomes peculiarly, often unbearably, distasteful when taken in amounts that anywhere nearly represent a sufficient exclusive diet. It hardly seems probable that any race has even "tried to live on sweet milk" alone, or even approximately so. Furthermore, milk of any kind or any preparation of it is at best a poor food as an exclusive diet for anything but an infant. We know very well, clinically, that babies a year or more old will become pale and flabby when fed on milk alone, possibly largely because, as Bunge has pointed out, milk in itself contains too little iron. There are other familiar objections to a sole milk diet.

Some of the fermented milks, notably koumiss, contain considerable quantities of alcohol and all of them have a decided taste. It would seem more probable that the reason fermented milks are used so freely among pastoral peoples would be that they have an acquired taste for it as a beverage, as some persons have for coffee, tea or beer, rather than that they ascribe superior nutritive or life-prolonging virtues to it as compared with sweet milk. There is a good deal of attractive theory but not a great amount of well-established fact concerning the effect of fermented milk in "intestinal toxemias," prolongation of life, etc. It has, for example, by no means been established that the striking results of buttermilk feeding in infancy are due to the presence of either the germs or the lactic acid, and not to the fact that a fat-free milk is being used.

TREATMENT OF COATED TONGUE

To the Editor:—What will clean up a persistently furred or coated tongue, one that stays coated all the time, is broad, flabby and moist, with a bad taste in the mouth every day in the year? What is the cause of this? Hepatic stimulants, tincture of nux vomica, hydrochloric acid and Canadian hemp do very little good. I should like to hear from some who have had success in such cases.

S. A. C., Virginia.

Answer.—Without more particulars it is hard to suggest a diagnosis, but some general rules may be given. Various explanations have been given of the coating on the tongue. The chief are: 1. The tongue is a part of the cutaneous system and is affected like the skin by general diseases, so that the coating is similar to an eruption of the skin. In such cases the eruption often persists after the disease which caused it has passed away. 2. The coating on the tongue may be due to local disorders of the teeth, oral mucous membrane, throat or nose. 3. The coating may rarely be due to some disease of the stomach but as a rule there is no direct relation between disease of the stomach and the fur on the tongue. 4. The coating on the tongue seems frequently to be related to the condition of the bowels, being probably the expression of a general poisoning resulting from the absorption of products of putrefaction by the intestinal mucous membrane.

In our correspondent's case he will need to seek out the cause. An examination of the stomach contents should be made, as the cause may lie in the stomach. If local disease is present it should be treated. Intestinal putrefaction should be prevented by the reduction or removal of protein, especially meat, from the diet, by the use of carbohydrate food, such as bread, corn-starch, cereals, etc., and by the use of laxatives, buttermilk, and if necessary intestinal antiseptics (phenylis salicylas). Locally the tongue should be cleaned with the tooth brush, and the use of an alkaline liquid like the liquor antisepticus alkalinus will facilitate the removal of mucus.

CUMULATIVE EFFECTS OF SUPRARENAL EXTRACT

In The Journal for July 31, 1909, a query was answered regarding the "Cumulative Effects of Suprarenal Extract." Further investigation of the subject has furnished the following additional data: Bouchard and Claude, 1902, experimented with a small number of rabbits, finding that they usually died from injections of 1 to 2 mg. per kilo, but if sublethal doses were first injected, as much as 4 mg. per kilo could be withstood by the animal. Abderhalden and Thies injected white mice with dextrosynthetic adrenalin, finding that it produced a resistance to doses of l-adrenalin 4 to 6 times that of the dose usually lethal.

Schultz of the Hygienic Laboratory of the Public Health and Marine-Hospital Service gives data in a bulletin entitled "Quantitative Pharmacological Studies. Adrenalin and Adrenalin-like Bodies," which indicate that small doses increase the animal's tolerance for subsequent doses of adrenalin. It is well known that small quantities of adrenalin sufficient to cause a rise in blood pressure have but a transient effect and do not influence the effect of subsequent doses if the latter are injected a few minutes after the return of the blood pressure to normal. It would seem from such data that initial injections of adrenalin either do not influence the effects of subsequent injections, or when they do so they render the animal more tolerant to its toxic action.

The Public Service

Medical Corps of the Navy

Changes for the week ended Aug. 7, 1909:

Minter, J. M., asst.-surgeon, ordered to the Naval Recruiting Station, Pittsburg, Pa.

Harlan, T., asst.-surgeon, detached from the Naval Recruiting Station, Pittsburg, Pa., and ordered to the Naval Hospital, Mare Island, Cal.

Harlan, T., asst.-surgeon, detached from the Naval Hospital, Mare Island, Cal., and ordered to the Asiatic Station, via the Naval Recruiting Station, Oklahoma City, Okla., and ordered home to wait orders.

Donelson, M., asst.-surgeon, detached from temporary duty in the Bureau of Medicine and Surgery, Navy Department, and ordered to the Naval Recruiting Station, Oklahoma City, Okla.

McMullin, J. J., acting asst.-surgeon, ordered to the Naval Hospital, Narragansett Bay, R. I

Murphy, J. F., P. A. surgeon, ordered to the Naval Hospital, Las Animas, Colo.

Wilson, H. D., surgeon, detached from the *Kentucky* and ordered to resume other duties.

Shaw, H., P. A. surgeon, detached from the Naval Station, Culebra, W. I., and ordered to the Navy Yard, Washington, D. C.

Rodman, S. S., P. A. surgeon, orders of July 27, detaching from the Naval Recruiting Station, Indianapolis, and ordering to the Naval Recruiting Station, Boston, *revoked*.

Stalnaker, P. R., P. A. surgeon, detached from the Navy Yard, Washington, D. C., August 10, and ordered to the Naval Station, Culebra, W. I.

Curtis, L. W., medical inspector, commissioned medical inspector from July 1, 1909.

Rodman, S. S., P. A. surgeon, detached from the Naval Recruiting Station, Indianapolis, and granted leave until September 25.

Eytinge, E. O. J., P. A. surgeon, commissioned passed assistant surgeon from May 24, 1908.

Munger, C. B., P. A. surgeon, commissioned passed assistant surgeon from July 7, 1908.

Medical Department of the Army

Changes for the week ended Aug. 7, 1909:

Connor, Clarence H., capt., granted leave of absence for four months, when relieved from duty in the Philippine Division; may return to the United States via Europe.

Miller, Edgar W., capt., granted leave of absence for 7 days.

Nichols, Henry J., 1st lieut., ordered to report at San Francisco, for examination for promotion, on completion and expiration of leave of absence, will proceed to New York City for duty as Attending Surgeon.

Persons, Elbert E., major, in addition to present duties, temporarily assigned as assistant to Chief Surgeon, Department of the East, and attending surgeon, headquarters, Department of the East.

Collins, Christopher C., major, granted leave of absence for four months.

Barber, John R., 1st lieut., relieved from duty at the Army Medical Museum, Washington, D. C., in time to proceed to San Francisco, and sail Oct. 5 for Philippines service; granted leave of absence for one month.

Purviance, William E., major, granted leave of absence for 25 days.

Woolley, Herbert C., 1st lieut., M. R. C., relieved from duty at Fort Davis, Alaska; will proceed home and then stand relieved from active duty in the Medical Reserve Corps.

Buchsbaum, Maurice, 1st lieut., M. R. C., relieved from duty at Fort D. A. Russell, Wyo., in time to proceed to San Francisco, and sail Sept. 5 for Philippine service.

Coffin, Harold L., 1st lieut., M. R. C., granted an extension of one month to his leave of absence.

Ware, William H., dental surgeon, ordered to Vancouver Barracks, Wash., for duty, at the expiration of his present leave of absence.

Boak, S. Davis, dental surgeon, relieved from duty at Vancouver Barracks, Wash., and [illegible] al., for duty.

Lauderdale, Clarenc[illegible] d to visit in succession for temporary [illegible] z., Whipple Barracks, Ariz., Fort Apa[illegible] N. M., returning then to Fort Logan, Colo.

Casaday, George H., dental surgeon, ordered from Fort Shafter, H. T., to the Presidio of Monterey, Cal., for temporary duty.

Public Health and Marine-Hospital Service

List of changes for the seven days ended August 4, 1909:

Bailhache, Preston H., surgeon, placed on "waiting orders" from November 1, 1909.

Banks, Charles E., surgeon, on being relieved by Surgeon E. K. Sprague, directed to proceed to Portland, Me., and assume command.

Kalloch, P. C., surgeon, on being relieved by Surgeon Charles E. Banks, directed to proceed to Memphis, Tenn., and assume command.

Wasdin, Eugene, surgeon, on arrival of Surgeon P. C. Kalloch, relieved from duty at Memphis, Tenn.

Brown, B. W., surgeon, granted a five days' leave of absence from July 29, 1909.

Brown, B. W., surgeon, on being relieved by P. A. Surgeon R. H. Creel, directed to proceed to Vineyard Haven, Mass., and assume command.

Sprague, E. K., surgeon, on being relieved by Asst.-Surgeon W. M. Bryan, directed to proceed to Key West, Fla., and assume command.

Lavinder, C. H., P. A. surgeon, granted 14 days' leave of absence from August 1, 1909.

Foster, M. H., P. A. surgeon, granted 1 day's leave of absence, July 27, 1909, on account of sickness.

Warren, B. S., P. A. surgeon, granted 14 days' leave of absence from August 1, 1909.

Creel, R. H., P. A. surgeon, on the arrival of Asst.-Surgeon James P. Leake, directed to proceed to Louisville, Ky., and assume temporary command.

Ashford, F. A., asst.-surgeon, directed to proceed to Washington, D. C., and report to chairman of board of medical examiners to determine his fitness for promotion to the grade of Passed Assistant Surgeon.

Herring, R. A., asst.-surgeon, leave of absence granted May 20, 1909, for 1 month and 4 days from June 5, 1909, amended to read 1 month and 6 days from June 5, 1909.

Bryan, William M., asst.-surgeon, relieved from duty at South Atlantic Quarantine Station, and directed to proceed to Southport, N. C., and assume command of the Cape Fear Quarantine Station.

Hasseltine, Hermon E., asst.-surgeon, directed to proceed to Buffalo, N. Y., and report to the medical officer in charge for duty.

Hunter, W. R., acting asst.-surgeon, granted 2 days' leave of absence from August 5, 1909.

Knight, Carlisle P., acting asst.-surgeon, granted 30 days' leave of absence from October 1, 1909.

Porter, Joseph Y., Jr., acting asst.-surgeon, granted 30 days' leave of absence from August 4, 1909, without pay.

Richter, H. C., acting asst.-surgeon, granted 15 days' leave of absence from July 29, 1909.

Story, H. C., acting asst.-surgeon, granted 30 days' leave of absence from September 1, 1909.

Weeks, Alanson, acting asst.-surgeon, leave of absence granted July 9, 1909, for 30 days from July 10, 1909, amended to read 30 days from July 19, 1909.

BOARD CONVENED

Board of medical officers convened to meet at the Bureau, August 5, 1909, for the examination of Asst.-Surgeon F. A. Ashford to determine his fitness for promotion to the grade of Passed Assistant Surgeon. Detail for the board: Asst.-Surgeon-General J. W. Kerr, chairman; Surgeon W. P. McIntosh; P. A. Surgeon J. F. Anderson, recorder.

Health Reports

The following cases and deaths of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended August 6, 1909:

SMALLPOX—UNITED STATES

Illinois: Danville, July 18-25, 2 cases.
Indiana: Fort Wayne, July 10-17, 3 cases.
Kansas: Kansas City, July 10-17, 1 case.
Kentucky: Lexington, July 17-24, 1 case; Newport, July 18-25, 1 case.
Louisiana: New Orleans, July 17-24, 1 case.
Michigan: Detroit, July 17-24, 1 case; Kalamazoo, 1 case.
Minnesota: Duluth, July 17-23, 3 case.
Missouri: St. Louis, July 17-24, 1 case.
Montana: Butte, July 15-22, 3 cases.
Ohio: Dayton, July 17-24, 1 case.

SMALLPOX—INSULAR

Philippine Islands: Manila, July 5-12, 1 case, 1 death.

SMALLPOX—FOREIGN

Algeria: Algiers, June 1-30, 2 deaths.
Brazil: Rio de Janeiro, June 13-27, 3 cases, 5 deaths.
Canada: Halifax, July 10-17, 2 cases.
China: Amoy, June 12-26, 19 deaths.
Egypt: Cairo, June 10-24, 3 cases, 1 death.
India: Calcutta, June 12-19, 7 deaths; Madras, June 19-25, 1 death; Rangoon, June 12-19, 3 deaths.
Indo-China: Saigon, May 29-June 12, 4 cases, 3 deaths.
Italy: Naples, June 4-11, 29 cases, 8 deaths.
Java: Batavia, June 5-19, 3 cases.
Mexico: Mexico City, May 29-June 26, 43 deaths; Monterey; June 11-18, 3 deaths.
Portugal: Lisbon, July 4-18, 22 cases.
Russia: Libau, July 3-10, 1 case, 1 death; Riga, 6 deaths; St. Petersburg, May 8-15, 20 cases, 5 deaths, June 19-July 3, 34 cases, 8 deaths.
Spain: Barcelona, July 5-12, 4 deaths; Vigo, July 3-10, 1 death.
Turkey: Constantinople, June 27-July 4, 1 case; Smyrna, May 27-July 1, 13 deaths.

YELLOW FEVER

Ecuador: Guayaquil, June 12-26, 9 deaths.

CHOLERA—INSULAR

Philippine Islands: Provinces, June 5-12, 77 cases, 52 deaths.

CHOLERA—FOREIGN

China: Amoy and vicinity, June 12-26, 3 cases, 7 deaths.
India: Calcutta, June 12-19, 23 cases; Madras, June 19-25, 1 death; Rangoon, June 12-19, 3 deaths.
Indo-China: Saigon, May 29-June 12, 5 cases, 2 deaths.
Russia: July 10-17, 1,020 cases, 421 deaths; St. Petersburg, 844 cases, 341 deaths.

PLAGUE—UNITED STATES

California: Alameda County, Sunol, Aug. 2, 1 case.

PLAGUE—FOREIGN

Chile: Antofagasta, June 26, 2 cases in lazaretto; Iquique, June 30, 2 cases in lazaretto.
China: Amoy, June 12-26, 210 deaths; Canton, July 5-19, 30 deaths.
Ecuador: Guayaquil, June 12-26, 9 deaths.
India: General, June 12-19, 885 cases, 766 deaths; Calcutta, 67 deaths; Rangoon, 36 deaths.
Indo-China: Saigon, May 29-June 12, 5 cases, 5 deaths.
Japan: Kobe, June 26-July 3, 1 case, 1 death; Yokahama, 5 cases, 1 death
Peru: June 26-July 3, 26 cases, 12 deaths.

Deaths

Charles F. Warner, M.D. Jefferson Medical College, Philadelphia, 1854; formerly president of the Minnesota Valley Medical Association; a member of the International Association of [illegible] it surgeon of the One Hundred and [illegible] of the Forty-eighth New York Vol- [illegible] Civil War; alderman of Mankato, Minn., and president of the council; for twelve years city health officer, and for two terms physician of Blue Earth county; local surgeon for the Northwestern and St. Paul systems, died at his home in Mankato, July 24, from senile debility, aged 76.

Albert H. Marvin, M.D. Western Reserve University, Cleveland, 1891; University of Pennsylvania, Philadelphia, 1892; of Cleveland; a member of the American Medical Association, American Academy of Ophthalmology and Oto-laryngology and Cleveland Academy of Medicine; lecturer on rhinology in the Cleveland College of Physicians and Surgeons, and surgeon to the Throat and Ear Dispensary of the Cleveland General Hospital; died at Chautauqua, N. Y., July 29, from nephritis, aged 42.

Robert J. Christie, M.D. University of Pennsylvania, Philadelphia, 1856; a member of the Illinois State Medical Society; formerly dean and professor of medicine in the Chaddock School of Medicine, Quincy, Ill.; local surgeon of the Hannibal and St. Joseph and St. Louis, Keokuk and Northwestern railways; consulting surgeon of the Blessing Hospital, Quincy; one of the best-known practitioners of western Illinois, died at his home in Quincy, July 27, from cholelithiasis, aged 78.

Victor J. Baccus, M.D. Northwestern University Medical School, Chicago, 1898; a member of the American Medical Association; professor of gynecology in Reliance Medical College, Chicago; formerly professor of surgery and head of the surgical department of the American College of Medicine and Surgery; surgeon to Frances Willard Hospital; died at the Policlinic Hospital, Chicago, August 10, after a long illness, aged 38.

George D. Dowkontt, M.D. Jefferson Medical College, Philadelphia, 1881; formerly editor and publisher of the *Double Cross* and *Medical Missionary Record*, and medical director of the International Medical Missionary Society; who is said to have established the first free dispensary in New York City; died at the home of his son in Brooklyn, July 31, from chronic bronchitis, aged 66.

Robert Masters Wilson, M.D. Long Island College Hospital, Brooklyn, N. Y., 1873; of Lincoln, Ill.; a veteran of the Civil War; president of the Brainerd District Medical Society in 1897; a member of the Illinois State Medical Society and surgeon to St. Clara's Hospital, Lincoln; died in that institution July 27, from cholelithiasis, aged 52.

Frank R. Hansen, M.D. Hospital College of Medicine, Louisville, 1898; formerly local surgeon to the Chicago, St. Paul, Minneapolis and Omaha Railway at Heron Lake, Minn.; secretary of the board of education of Lakefield, Minn.; is reported to have died in the Jackson county jail, Lakefield, July 29, aged 37.

Augustus Lewis, M.D. University of Tennessee, Nashville, 1879; a member of the Kentucky State Medical Association; for many years a U. S. pension examining surgeon at Central City, Ky.; a veteran of the Civil War; died at his home in Greenville, July 27, from lung disease, aged 70.

Ralph B. Hanahan, M.D. Medical College of South Carolina, Charleston, 1886; of Winnsboro, S. C.; a member of the American Medical Association; for whose services during the Charleston earthquake, a medal was awarded by the city of Charleston; died at his home, July 30, from heart disease, aged 48.

Markwell Seward Curdy, M.D. Chicago Homeopathic Medical College, 1884; in 1893 and 1902, health officer of Corning, N. Y.; formerly attending physician to Corning Hospital and for many years proprietor of the Highland Pines Sanitarium, died at his home in Ithaca, N. Y., July 25, from paralysis, aged 50.

Thaddeus Donahue, M.D. Kentucky School of Medicine, Louisville, 1867; a member of the Tennessee State Medical Association; major and surgeon during the Civil War; for several years a member of the local board of U. S. pension examining surgeons; died at his home in Memphis, July 25, aged 74.

Henry Gordon Forbes, M.D. New York University, New York City, 1866; a contract surgeon in the Army during the Civil War; for three terms a member of the board of aldermen of Chicopee Falls, Mass.; died at his home in that city, July 30, from cirrhosis of the liver, aged 69.

Harvey Monroe Young, M.D. University of Alabama, Mobile, 1893; a member of the Medical Association of the State of Alabama; formerly health officer of Dothan, Ala., and physician to Houston county; died suddenly at his home in Dothan, July 27, from dengue fever.

Charles S. Morton, M.D. University of Virginia, Charlottesville, 1854; for many years a practitioner of Pamplin City, Va.; surgeon of the Tenth Georgia Infantry, C. S. A., during the Civil War; was killed by a railway train, near Lynchburg, Va., July 28, aged 77.

Percy Stansbury, M.D. Baltimore University, 1894; formerly of Baltimore; a surgeon in the volunteer service during the Spanish-American War, with service in Cuba; died suddenly at his home at Wingate's Point, Md., July 26, from heart disease, aged 42.

J. L. Johnston, M.D. Physio-Medical College of Indiana, Indianapolis, 1898; of Los Angeles, Cal.; died in the Mine Operators' Hospital at Searchlight, Nev., July 23, from the effects of a fall into the shaft of the Duplex Extension mine, aged 65.

Albert M. Curry, M.D. University of Pennsylvania, Philadelphia, 1875; of Brooklyn, N. Y.; a member of the Medical Society of the State of New York; died suddenly on the beach at Atlantic City, N. J., July 26, from heart disease, aged 59.

George C. Burton, M.D. Louisville, (Ky.) Medical College, 1881, Washington, D. C.; a member of the Medical Association of the District of Columbia; died at his old home in Mitchell, Ind., July 22, from cerebral hemorrhage, aged 52.

Wilbert G. McIntyre, M.D. Trinity Medical College, Toronto, 1901; M. C. P. and S., Ont., 1892; member of parliament for Strathcona, Alberta; died in the Strathcona Hospital, July 21, after an operation for disease of the kidney.

Grant Cullimore, M.D. Rush Medical College, Chicago, 1885; an oculist and aurist; at one time secretary of the Oklahoma Territorial Board of Health; died at his home in Oklahoma City, July 29, from typhoid fever, aged 47.

Yewell Dalton Scales, M.D. (license, Ill., 1878); of Springfield, Ill., assistant surgeon in a Tennessee regiment, C. S. A., during the Civil War; died in St. John's Hospital, Springfield, July 21, from cerebral hemorrhage, aged 65.

Archibald G. Kinkhead (license, Ill., years of practice, 1878); a member of the Illinois State Medical Society; a surgeon at Camp Yates, Springfield, Ill., during the Civil War; died at his home in Greenfield, Ill., July 23, aged 76.

Oliver H. Buford, M.D. Medical College of Georgia, Augusta, 1889; formerly an acting assistant surgeon, U. S. Army; a member of the Medical Association of Georgia; died at his home in Cartersville, July 30, aged 51.

George Heywood, M.D. Harvard Medical School, Boston, 1887; a member of the Medical Society of the State of New York; died suddenly at his home in New York City, July 30, from cerebral hemorrhage, aged 47.

Samuel Robert Dunlop, M.D. College of Physicians and Surgeons, New York City, 1890; of Trenton, N. J.; died in the Hudson Street Hospital, New York City, January 29, from morphin poisoning, aged 42.

Henry Hull, M.D. University of Michigan, Ann Arbor, 1872; a veteran of the Civil War; for eleven years postmaster of Ravenna, Mich.; died at his home, July 28, from cerebral hemorrhage, aged 62.

James A. Diddle (license, W. Va., years of practice), formerly of Winifrede, W. Va.; physician for the Coke-Coal company near Meadowbrook, W. Va., died recently at East Bank, W. Va., aged 66.

Julius Nelson Fraser, M.D. Laval University, Montreal, 1874; of Kankakee, Ill.; died at the West Side Hospital, Chicago, July 27, from tuberculosis, after a surgical operation, aged 67.

Joseph H. Price, M.D. Jefferson Medical College, Philadelphia, 1877; a member of the Medical Society of the State of Pennsylvania; died at his home in DeHaven, July 27, aged 56.

George Paul Guilford, M.D. St. Louis (Mo.) Medical College, 1870; a veteran of the Civil War; died at his home in Owosso township, Mich., July 25, from cerebral hemorrhage, aged 68.

John W. Miller, M.D. American Medical College (Eclectic), St. Louis, 1897; (license, Ill., years of practice, 1888); of Madison, Ill.; died in Edwardsville, Ill., recently, aged 71.

George W. Briggs, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1876; formerly of Chapin, Ill.; died at his home near St. James, Mo., July 25, from nephritis.

Edwin C. Hunt, M.D. Tulane University, New Orleans, 1891; a member of the Mississippi State Medical Association; died at his home in Vicksburg, July 24, aged 42.

Will L. Chester, M.D. University of Louisville (Ky.), 1879; of Jackson, Tenn.; died in a hospital in Memphis, Tenn., July 26, from disease of the stomach, aged 50.

Charles Dustin Hunking, M.D. Harvard Medical School, Boston, 1877; of Haverhill, Mass.; died at his summer home at Hampton Beach, N. H., July 23, aged 59.

Robert C. Carter, M.D. Missouri Medical College, St. Louis, 1868; a member of the Missouri State Medical Association; died at his home in Higginsville, July 5.

Andrew Jackson Swaney, M.D. New York University, New York City, 1851; died at his home in Gallatin, Tenn., July 20, from heart disease, aged 77.

Samuel E. Dyke, M.D. Louisville (Ky.) Medical College, 1875; died at his home in Spring Valley, Ohio, July 27, from heart disease, aged 62.

Melvin H. Fitts, M.D. Eclectic Medical Institute, Cincinnati, 1873; died at his home in Martin, Tenn., July 21, from cerebral hemorrhage, aged 67.

William Conner, M.D. Jefferson Medical College, Philadelphia, 1892; died at his home in Philadelphia, July 19, from paralysis, aged 59.

John M. Griffin, M.D. Tulane University, New Orleans; died at his home in Hillsboro, Tex., February 13, from nephritis, aged 77.

John McArthur Dunsmore, M.D. McGill University, Montreal, 1870; died recently at his home in Stratford, Ont., aged 77.

Marriages

Ira C. Bowman, M.D., to Miss Helen H. Ogden, both of Philadelphia, July 29.

Galen K. Hassenplug, M.D., to Miss Helen A. Sarconi, both of Denver, July 26.

Ira G. Gasser, M.D., to Miss Lillian H. Ryan, both of Philadelphia, July 29.

Helen McNichol, M.D., and Edward A. English, both of Philadelphia, July 26.

Walter F. Rochelle, M.D., Jackson, Tenn., to Miss Kathleen McCorry, June 30.

Carl Ludwig Larson, M.D., to Miss Mary Alice Prosser, both of Butte, Mont., July 19.

Ralph S. Chamberlain, M.D., Denver, to Miss Mollie J. Dorsey, at York, Pa., July 27.

George E. Parsons, M.D., Elk River, Minn., to Miss Jessie Helen Horn, of St. Paul, July 26.

Francis Schill, Jr., M.D., to Miss Olive Virginia Shaffer, both of Johnstown, Pa., June 30.

Donald Ross McIntyre, M.D., Gwinn, Mich., to Miss Carolyn Merritt King of Milwaukee, August 3.

John Wilson MacConnell, M.D., Davidson, N. C., to Miss Agnes H. Doyle, at Baltimore, July 28.

Thomas Victor Batchelor, M.D., Bovina, Miss., to Miss Maria Louise Young of Vicksburg, Miss., July 20.

Evahn Russell Walker, M.D., Marshalltown, Iowa, to Miss Mae Bower, at West Union, Iowa, recently.

D. Ashley Turner, M.D., Goldfield, Nev., to Miss Charlotte Schultz, of Walla Walla, Wash., at Los Angeles, Cal., July 19.

Medical Education and State Boards of Registration

Reciprocity with Vermont

Dr. W. Scott Nay, secretary of the Vermont State Board of Medical Registration, states that Vermont now has reciprocal relations with District of Columbia, Illinois, Indiana, Maine, Maryland, Michigan, New Hampshire, New Jersey, New York, North Dakota, Ohio, Texas, Wisconsin and Wyoming.

Present Status of State Board Requirements

Elsewhere in this issue it will be noted that 50 medical colleges have adopted requirements of preliminary education beyond a four-year high-school education. It will be particularly interesting, therefore, to note advances in requirements made recently by state medical examining boards. Some of these requirements are graphically presented by the accompanying charts and the essential features of the various practice acts are shown in Table A.

Table B shows what states have established reciprocal relations with other states.

Table A

Essential Features of State Laws and Conditions Surrounding Medical Licensure

State.	Examinations only—Graduation not essential	Diploma and Examination.	Preliminary Education.				Medical Education.						Has Reciprocity with Other States.	Examining Boards Separate.	Exam. Board Nomt'd or App'd by State Med. Soc.	Examination Fee.	Certificate and Recording Fee.

* Previous to or at the time of matriculation.

† Will accept a diploma without examination if from a recognized college.

PRELIMINARY EDUCATION

Chart I shows the provision made by the various states in regard to the preliminary education of applicants. Six states have adopted preliminary requirements equal to one or two years of work in a college of liberal arts in addition to a four-year high school education, thereby supporting the better class colleges with similar requirements. These are:

State Examining Board of	No. of Years Required	Affects Students matriculating	Affects all Applicants after
North Dakota	2	1907-08	1911
South Dakota	1	1907-08	1911
Minnesota	2	1908-09	1912
Colorado	1	1908-09	1912
Connecticut	1	1910-11	1914
Kansas	1	1910-11	1914

There are twenty-two states having *preliminary* requirements stated as a four-year high school education or its "equivalent," which is intended to mean a four-year high school course which has been preceded by eight years in the elementary grades. These states are:

California
Delaware
Illinois
Indiana
Iowa
Kentucky
Maine
Michigan
Missouri
Nebraska
Nevada
New Hampshire
New Jersey
New Mexico
New York
Ohio
Pennsylvania
Texas
Utah
Vermont
West Virginia
Wisconsin

In five states preliminary standards are provided for but which are less than a four-year high school education, these states being:

Arkansas
Maryland
Oklahoma
South Carolina
Texas

In three states, Idaho, Montana and North Carolina, no standards have been fixed, although the boards have authority to establish the standard. In North Carolina an amendment to make the preliminary requirement a four-year high school education was recently defeated by a plea "for the poor boy who wants to study medicine."

There still remain thirteen states having no provision in the law for preliminary education. These states are:

Alabama
Arizona
District of Columbia
Florida
Georgia
Louisiana
Massachusetts
Mississippi
Oregon
Tennessee
Virginia
Washington
Wyoming

In the fourth column of Table A it will be noted that in six states the examining boards pass on all the entrance credentials of medical students previous to, or at the time of matriculation, and conduct all entrance examinations. These states are:

Indiana
Kentucky
Michigan
New York
Ohio
Wisconsin

The weakest point in the American system of medical education still remains the low requirements of preliminary education and, speaking generally, no requirement is so poorly enforced by our examining boards, chiefly because of the difficulty of giving fair value to the credentials from our endless variety of secondary schools. Investigation reveals that the "equivalent" of a four-year high school education in several states may mean almost anything from the fair equivalent down to a 20-week course in a night school or less.

Five years ago fourteen states were allowing non-graduates to take examinations and secure licenses to practice medicine. Now all states require that candidates must be graduates of medical schools except three, these, as shown in Chart 2, being Massachusetts, Mississippi and Tennessee.

RECOGNITION OF MEDICAL COLLEGES

Chart 3 shows what state boards have been given authority to withhold recognition from low grade medical colleges. Some laws give authority but at the same time provide educational standards so low as to make the authority ineffective. Others merely provide that the college must be "legally chartered" which is of little effect since even a number of notorious diploma mills were "legally chartered." There are twenty-seven states, however, which have apparently given their boards unhampered authority to refuse recognition to medical schools not doing satisfactory work. These states are:

Colorado
Connecticut
Delaware
Idaho
Illinois
Iowa
Indiana
Kansas
Kentucky
Maine
Michigan
Minnesota
Missouri
Montana
Nebraska
New Hampshire
New Mexico
New York
North Dakota
Ohio
Rhode Island
South Carolina
South Dakota
Texas
Vermont
West Virginia
Wisconsin

Fourteen states are given authority which for various reasons is more or less limited. These states are:

Arizona
Arkansas
California
District of Columbia
Georgia
Louisiana
Nevada
New Mexico
North Carolina
Oklahoma
Oregon
Utah
Washington
Wyoming

There still remain eight states where the examining boards are not given legal authority to protect the people of their states from graduates of diploma mills or low grade medical colleges. These states are:

Alabama
Florida
Maryland
Massachusetts
Mississippi
Pennsylvania
Tennessee
Virginia

RECIPROCITY

Chart 4 shows that only thirteen states remain which have not entered into reciprocal relations with others. These states are:

Alabama
Arizona
Connecticut
California
Florida
Idaho
Massachusetts
Mississippi
Montana
Oregon
South Dakota
Rhode Island
Washington

Alabama and South Dakota have legislation providing for reciprocity but as yet no reciprocal relations with other states have been reported.

Table B shows which states have reciprocal relations and the basis on which such reciprocity has been established. During 1908, 1,092 licenses were granted through reciprocity as compared with 989 in 1907 and 685 in 1906. The figure "1" indicates that reciprocity is on the basis only of a written examination while the figure "2" indicates that reciprocity is on the basis of either a written examination or of a diploma without examination. If the applicant was originally registered without examination prior to the date when the state in which he desires re-registration began requiring examination of all applicants, he is eligible in states with the figure 2. The dates in the second column show when the states began requiring examinations of all applicants.

MULTIPLE BOARDS

The number of states having more than one board of medical examiners has been gradually reduced until now only

Key: 1, Reciprocates on the basis of an examination only. 2, Reciprocates on the basis either of a diploma or of an examination.
NOTE A.—Reference should also be made in the preceding pages to the paragraph concerning reciprocity in the law of each state.

ten remain. These states and the number of boards in each are as follows:

Arkansas, 3.
Connecticut, 3.
Delaware, 2.
District of Columbia, 3.
Florida, 3.
Georgia, 3.
Louisiana, 2.
Maryland, 2.
New Hampshire, 3.
Pennsylvania, 3.

The division of the responsibility for the safeguarding of public interests always leads to confusion and adds to the difficulty of upholding any fair standard of licensure.

OSTEOPATHY

Every new school of medicine which tries to secure the right to practice medicine invariably holds standards of preliminary and medical education lower than those already in the field. That is the chief argument against them. So the new sect, osteopathy, which, under the pretext that its followers were "not practicing medicine," has secured favorable legislation in a considerable number of states (Chart 6), upholds practically no standards for admission and gives at most only a three-year course in medicine. The legal status is discussed more in detail below:

ONE STANDARD NECESSARY

One thing should be clearly borne in mind in all discussions of medical sects, namely: Regardless of the methods or limitations of treatment employed, practitioners are alike in that they must make diagnoses—must differentiate between health and disease. To treat a disease without knowing what it is, is merely guesswork, is unscientific, is a dangerous procedure and is an imposition on the patient. For these reasons there should be one standard set for all practitioners of medicine regardless of the methods of treatment, and this standard should be sufficiently high to guarantee that the practitioner is able to properly diagnose diseases. If he can comply with that standard he should be granted a license and allowed to practice by whatever method he chooses. If he can not comply with that standard he is a menace to the lives of any who would be unfortunate enough to be his patients, and for that reason should not be allowed to practice.

Present Legal Status of Osteopathy

Closely allied to the regulation of the practice of medicine is the problem of the regulation of the various sects and fads which are constantly arising. The most conspicuous one just at present is the so-called "school of osteopathy," the peculiar teachings of which are too well known to require discussion. With the scientific fallacies of this cult we are not at present concerned, but simply with the present legal status of the followers of this school in the various states.

Examination of the existing laws shows an interestingly contradictory and peculiarly characteristic condition. In some states, the practice of osteopathy has been legally decided to be the practice of medicine, while in other states it has been decided by equally weighty and learned authorities that it is not the practice of medicine. Naturally, in most of those states in which a separate board of osteopathic examiners has been created, the courts have held that osteopathy was something separate and distinct from the practice of medicine, while in those states in which osteopaths have been added to the existing boards, the courts have held that osteopathy was simply one form of the practice of medicine.

In seventeen states, the existing laws authorize a separate board, to examine and license practitioners of osteopathy. These states, with the year of the adoption of the law, are as follows: Arkansas, 1903; Connecticut, 1901; Florida, 1909; Idaho, 1907; Louisiana, 1908; Michigan, 1903; Minnesota, 1903; Missouri, 1907; Montana, 1905; Nebraska, 1909; New Mexico, 1905; North Carolina, 1907; North Dakota, 1909; Pennsylvania, 1909; South Dakota, 1907; Tennessee, 1905; Vermont, 1904.

In eleven states, the law authorizes the appointment of an osteopath on the state board. These states, with the date of the passage of the law, are: California, 1907; Indiana, 1905; Iowa, 1902; Kentucky, 1904; New York, 1907; Oklahoma, 1907; Oregon, 1907; Texas, 1907; Utah, 1907; Washington,

CHART I.—STATE BOARD REQUIREMENTS OF PRELIMINARY EDUCATION

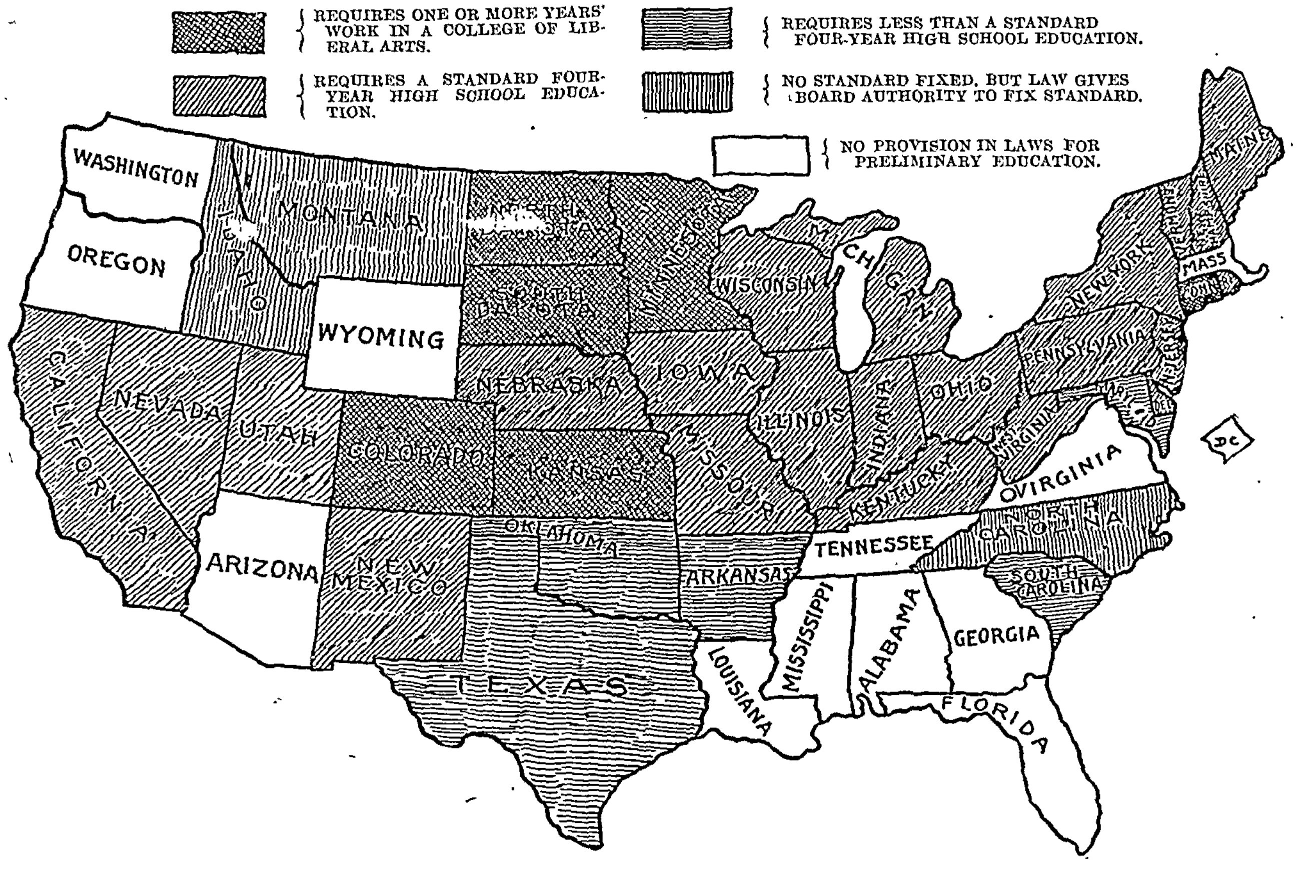

Chart 2.—States Requiring Graduation from a Medical College

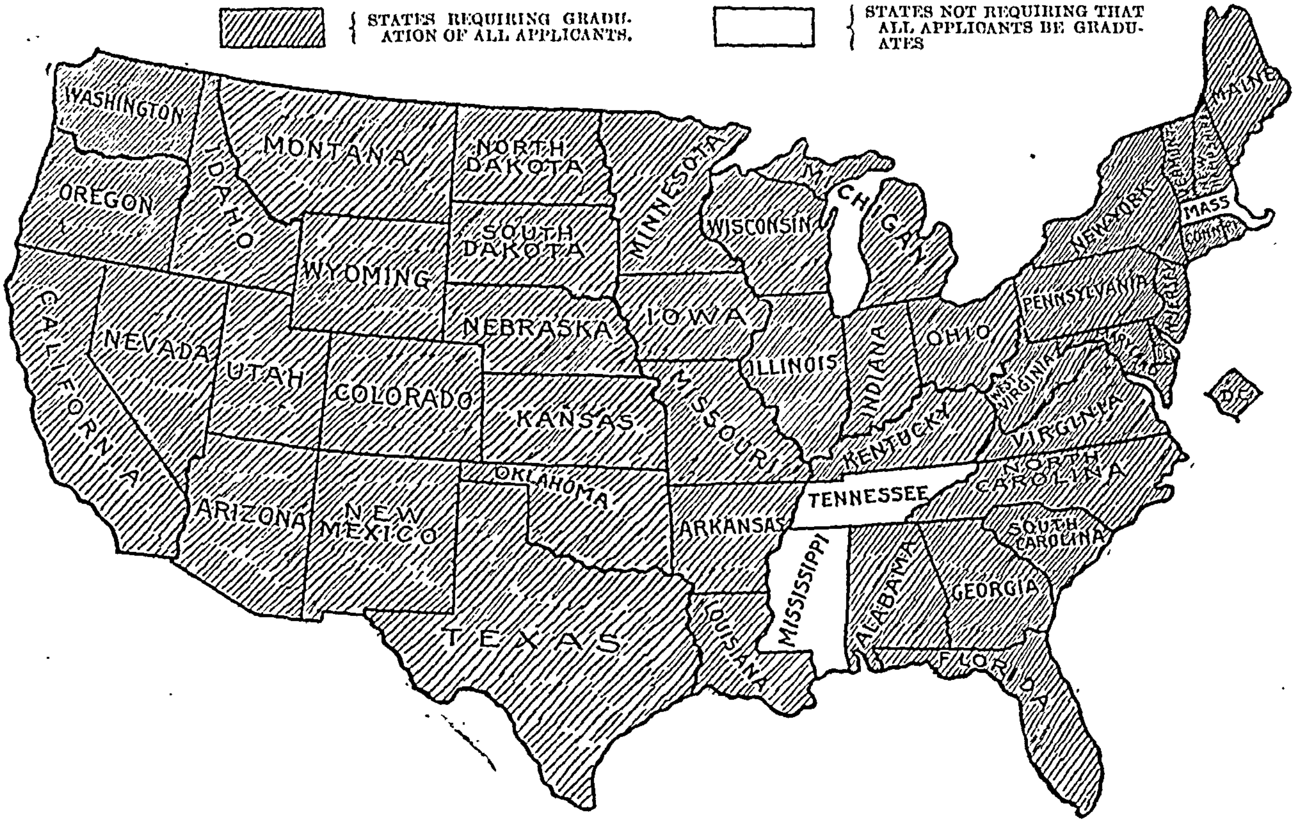

Chart 3.—State Boards Having Authority to Refuse Recognition to Low Grade Medical Colleges

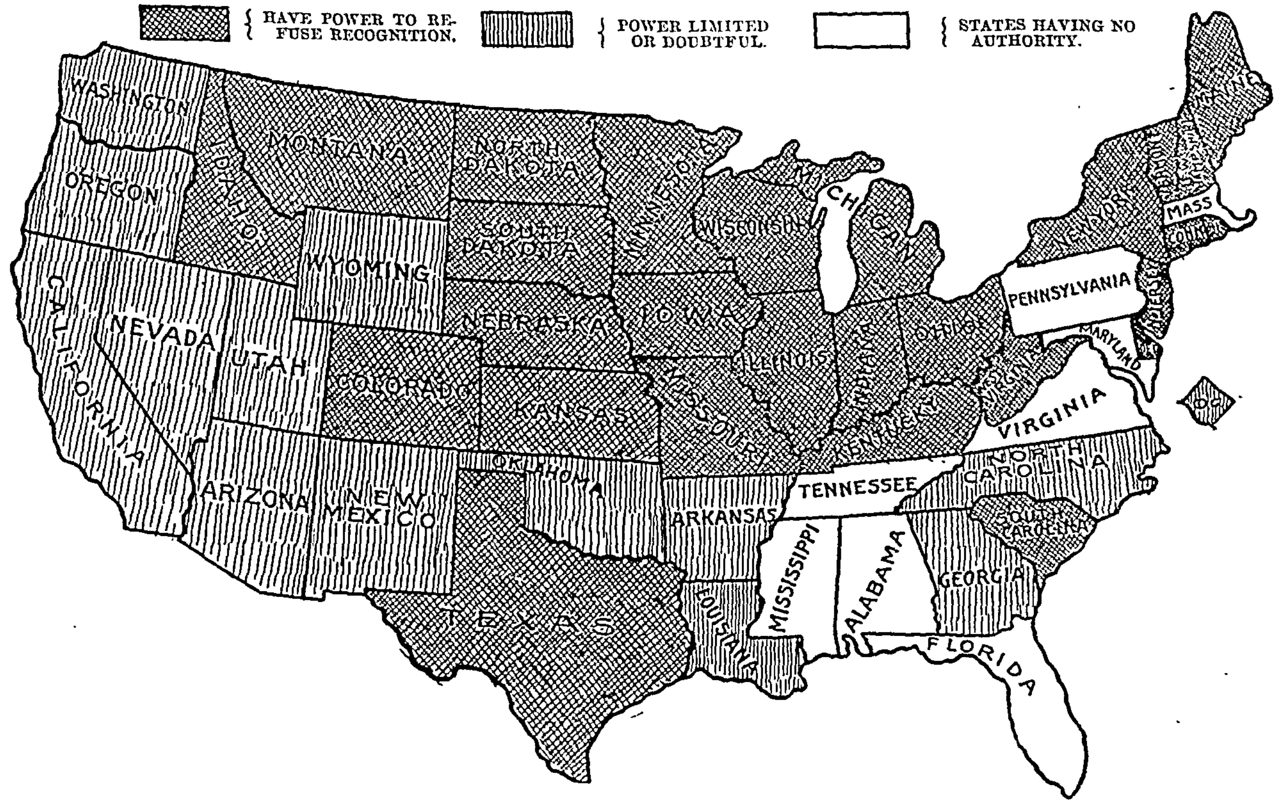

1909; Wisconsin, 1903. In Iowa, while authorized, the governor has not yet appointed an osteopathic member.

In two states, Colorado and Maryland, osteopaths are exempt from the operation of the medical practice act. In nine states, the examining board is authorized to examine and register them as osteopaths. These states are: Delaware, 1907; Kansas, 1901; Massachusetts, 1909; Nebraska, 1905; Ohio, 1906; South Carolina, 1904; Washington, 1903; West Virginia, 1907; Wyoming, 1905. In Delaware, Nebraska and Ohio the board is authorized to call on an osteopath to assist in the examinations. In nine states there is no existing regulation regarding this sect. These states are: Alabama, Arizona, District of Columbia, Georgia, Maine, Mississippi, New Hampshire, Nevada and Rhode Island. In Alabama and Arizona, osteopaths can secure licenses on taking the same examination as other applicants.

Regarding the legal status of osteopathy as a system, in the following states it has been declared to be the practice of medicine, either by statutory enactment or by decision of the courts: Alabama, Arizona, California, Delaware, Indiana, Iowa, Kentucky, New York, Ohio, Texas, Utah, Virginia, West Virginia, Wisconsin, Wyoming. In the following states it has been declared not to be the practice of medicine: Arkansas, Colorado, Connecticut, Georgia, Idaho, Illinois, Kansas, Louisiana, Michigan, Minnesota, Missouri, Montana, Nebraska, North Carolina, Oklahoma, Oregon, South Carolina, South Dakota, Tennessee and Vermont, making fifteen states in which the osteopath is a practitioner of medicine and twenty states in which he is not.

The absurdity and utter inconsistency of such a situation is apparent, the entire fallacy, from a scientific standpoint, lying in the confusion by courts, lawyers, and legislators of therapeutic measures and systems of practice with so-called "schools of medicine," as well as the equally common absurdity of restricting one's conception of the meaning of the term "practice of medicine"—which has been adopted as a convenient phrase to describe the work of those who care for the sick—as being limited to the administration or use of drugs. This fallacy arises from the fact that, in the popular mind, the most obvious means used for treating diseases has gradually come to stand for not only the *entire* system of treatment but also for the *entire* mass of scientific knowledge.

From a legal point of view, the absurdity of sectarian legislation lies in the establishment of two standards of requirements for the same privilege. The state, in the exercise of its police power to regulate or restrict occupations, professions and trades, requires that each individual desiring to engage in the work of treating the sick, must present certain qualifications and must satisfactorily pass an examination test of a certain standard. Such a standard of qualification having been established, it is plainly inequitable for the state to adopt a law admitting individuals to the same privileges on a lower basis of qualification, since such favoritism constitutes class legislation and is clearly unconstitutional. In other words, there is no more legal justification for two standards for the practice of medicine in any state than there is for two standards for the practice of law, nor has a state any more right to recognize sectarianism in medicine than it has to recognize sectarianism in the legal profession, or in religious matters. We can easily conceive of the reception which would be afforded an individual who would present a bill in any of our state legislatures asking that a certain sect or class of men, unlearned in the law and unrecognized in legal circles, be authorized to practice law, to appear before the courts and to exercise the rights and privileges of attorneys with one-half or two-thirds of the intellectual and technical training required by the bar association of the state. Such a bill would be laughed out of the legislature, even if any member had the temerity to present it. Yet this is exactly the situation which sectarian medical laws create, so far as state recognition of medicine is concerned. The reason why state legislatures have committed absurdities along medical lines which they would not tolerate for a moment on legal subjects, is that the majority of the members of the legislature are informed on legal questions and consequently can legislate intelligently, while on medical subjects they are entirely uninformed and are consequently more easily influenced by their prejudices and personal relations.

Book Notices

Text-Book of Embryology. By Frederick Randolph Bailey, A.M., M.D., Adjunct Professor of Histology and Embryology, College of Physicians and Surgeons (Med. Dept. Columbia Univ.) and Adam Marion Miller, A.M., Instructor in Histology and Embryology, College of Physicians and Surgeons (Med. Dept. Columbia Univ.). Cloth. Pp. 672, with illustrations. Price, $4.50. New York: William Wood & Co., 1909.

This book, while including subjects of interest to the general student of embryology, is primarily intended "to present to the student of medicine the most important facts of development, at the same time emphasizing those features which bear directly on other branches of medicine." It is accordingly divided into two parts and an appendix. Part I deals with general development. Part II with the development of the adult tissues and organs. To each chapter there is appended a good bibliography and "practical suggestions" for laboratory work, embracing the subjects dealt with in that chapter. In each chapter of Part II there is added under "anomalies" an embryologic consideration of malformations peculiar to the structures taken up in the respective chapter. There is also a special chapter on teratogenesis in which are discussed duplicity of structures and fetus, defects in fetus and the causes underlying the origin of monsters.

Part I includes a discussion of the cell, mitosis, the male and female, sex cells, maturation, fertilization, cleavage, the germ layers, the fetal membranes and the development of the external form of the body. While this is primarily a text-book of human embryology, yet, owing to the scarcity of early human embryonic material, early development as seen in the lower forms is of necessity resorted to. The simpler types of development, such as that of the Amphioxus, the chick and the frog constitute the basis for the consideration of the development of the germ layers. It is to be regretted that Chapter V (cleavage) and Chapter VI (the germ layers) do not compare favorably with the remainder of the book. These subjects form almost the entire basis for the field of embryology, and any inadequacy or errors in this part of a text-book are particularly serious.

Part II embraces the development of the connective tissue, the skeletal, muscular, vascular, respiratory, circulatory, urogenital, integumentary, and nervous systems, the alimentary tube and appended organs, the organs of special sense, and teratogenesis, and is a decided improvement over Part I. This is especially true of Chapter XVII (the nervous system), which is the best part of the book. Here a very difficult subject is treated in a comprehensive yet lucid manner, which places it easily within the grasp of the average medical student. One would naturally expect to find the name of the author of this chapter (Dr. Oliver S. Strong) on the title-page. The nervous system covers practically one-fifth of the book, yet Dr. Strong is only slightly mentioned in the preface. The development of the vascular system (Chapter X) is also well brought out.

There are 515 illustrations in the text. In Part II they are in the main good, well selected, and compare favorably with those of the best English text-books of embryology. The general plan of the book is an excellent one. but is perhaps better suited to a more extensive work on the subject. It is doubted if sufficient time can be spared from an already well-crowded curriculum to cover the subject of embryology as outlined in this text. One would think that the authors, in writing a general text for medical students, had shown a slight tendency to place it beyond their grasp; since an adequate knowledge of the great variety of subjects dealt with and of such subjects as teratogenesis and the causes underlying the origin of monsters, can not be obtained from so brief a text. A great deal of supplementing by lectures and original articles would be required, which would require more time than can be ordinarily devoted to the subject. The book is well printed. Several technical errors (due probably to oversight) and apparent contradictions in Part I will doubtless be corrected in the first revision of the book.

The Errors of Mind-Healing. By Reinhold Willman, M.D., St. Joseph, Mo. Cloth. Pp. 179. Price, $1. St. Joseph, Mo.: The Advocate Publishing Co.

Dr. Willman, with the praiseworthy intention of setting forth, as he says, the view that the physician can and must take of the Scriptural records of miracles, argues to show that there is nothing in common between those miracles and the modern use of hypnotism, suggestion, faith healing, etc. Accepting the accuracy of the records, which a believer in Christianity is obliged to do, he seems to us to be on the right track. There are some clergymen and critics who attempt to reconcile the New Testament miracles with modern science and account for them as far as they can by known phenomena. Dr. Willman shows the fallacy of this and makes it clear that their only alternative to accepting the Biblical statements is to doubt the records. In the latter part of his book he takes up modern faith healing, Eddyism, Dowieism, etc., and shows up the commercial spirit that underlies nearly all of them. We wish he could have had his book revised to free it from certain slips in the author's English as well as numerous typographical errors. His quotations from Mrs. Eddy's "Science and Health" and the text-books of Emmanuelism are rather apt in support of his argument.

The Greatest Good of Mankind: Physical or Spiritual Life. By William Wenzlick, LL.B., M.D. Cloth. Pp. 374. Price, $1.50 net. Chicago: Published by the Author, 1206 Lawrence Ave.

This book is made up of alternate opposed views in regard to questions of sociology, religion, etc., by two supposed writers, Dr. Fact and the Reverend Faith. Dr. Fact, the materialist, critic of the Bible after Tom Paine, and opponent of prohibition, represents Dr. Wenzlick's sentiments, while the Reverend Faith is a severe specimen of the cloth and not at all such a lovable representative of religion as its friends would prefer to have speak in refutation of the scoffer's sophistries. This method of setting up a man of straw or arguing with a dummy is a convenient one because the disputant has in it altogether his own way. We very much doubt its effectiveness in argument, however. Dr. Wenzlick has evidently done a large amount of reading of the Scriptures, but in a very critical and hostile spirit, which would probably give offense to a large majority of the reading public if his book were so fortunate as to come under their notice. In fact, a large proportion, we believe, of those who agree with him more or less in his ideas of personal liberty, so-called, would take offense at his sentiments in some other lines. His estimate of the value of alcohol and the blessing of the saloon will not be shared by the majority of conservative physicians.

Society Proceedings

ASSOCIATION OF AMERICAN TEACHERS OF THE DISEASES OF CHILDREN

Third Annual Meeting, held at Atlantic City, June 7, 1909

(Concluded from page 477)

Personal Relations of Teacher and Student

Dr. Edward J. Wynkoop, Syracuse, N. Y.: In many colleges, pediatrics is taught only in the fourth year. It is a most important subject for the young practitioner, inasmuch as two-thirds of his practice during the first few years will consist of accidents and diseases occurring among children. Only by the institution of more clinical work in the college can we hope to come in more personal contact with the student. The identity of the individual student is not always known. A personal knowledge of each man should be insisted on. The classes should be divided into sections of ten men each so as to establish personal relationship with each man. Teachers in medical colleges should take more interest in the social side of the student's life, and teachers should likewise bear in mind that they owe the student something more than merely class-room instruction.

DISCUSSION

Dr. A. C. Cotton, Chicago: The tendency to-day is toward larger teaching faculties so as to bring the students in touch with the subject in smaller classes. The teacher has an opportunity, therefore, of studying the actual needs of the individual student. The large staffs of the hospitals connected with our colleges enable the assistants to report to the chief of the staff the needs of the various students. Frequent quizzes, and the visiting of the staff by the students, partly fills the void created by the departed preceptor who was so valuable in olden times.

Dr. A. Jacobi, New York City: The only place to teach medicine is at the bedside of the patient, or, if the college has a hospital connection, from material secured from the outpatient department. Unfortunately, most of our medical schools have no hospitals. We have too many students, or, perhaps, we have too many colleges. Large schools with large hospitals require a large teaching staff, and the aim of the teacher should be first, to secure suitable material for instructing the students, and, second, to divide the classes into sections of ten or twelve men each, so as to impart almost individual instruction.

Report of the Committee on the Teaching of Pediatrics

Dr. S. W. Kelley, Cleveland: Each college should have a chair of pediatrics with full professorship. Pediatrics should be studied in the junior and senior years. The course should be graded and include the anatomy and physiology of infancy and all the affections of childhood both medical and surgical. The surgical side of pediatrics may be taught in the chair of surgery. A large part of the teaching should be clinical. The classes should be divided into sections of ten or twelve men. No college without a hospital or dispensary for children is prepared to successfully teach diseases of children.

How Should the Percentage Method of Milk Modification be Taught?

Dr. J. Finley Bell, Englewood, N. J.: The chemical and physical constituents of cow's milk as compared to those of mother's milk are so different that the percentage method as taught to-day does not solve the problem of milk modification. The proteid and fat percentages are at fault. The student in college should be taught how to examine specimens of milk. We should teach general principles only, permitting the student to form his own conclusions. The universal adoption of the metric system will simplify the matter and render the results more accurate. In preparing the formulas a knowledge of the physiologic needs of the infant is necessary.

What Should Be Taught Concerning Proprietary Foods and Condensed Milk?

Dr. I. L. Poloske, Detroit: The students in our colleges should be taught the difference between cow's milk and proprietary foods. Proprietary foods are deficient in fat and have an excess of carbohydrates. Condensed milk and proprietary foods predispose the baby to scurvy, rickets, constipation and the various infectious diseases. All proprietary foods are rich in flour and dextrin. The physician must know the value of the food he prescribes and with patented foods this is impossible. Condensed milk should be used in catarrhal diseases where cow's milk can not be used. The enormous number of proprietary foods on the market is due to the large number of physicians who prescribe them.

DISCUSSION

Dr. H. M. McClanahan, Omaha: There are two reasons why proprietary foods are used: 1. They are advertised directly in the home. 2. A large percentage of the profession is indifferent as to the methods of milk modification. It is a very good plan to warn students regarding the harmful effect of these patented foods.

What Should Be Taught About Mixed Feeding?

Dr. H. M. McClanahan, Omaha: Science and art can not prepare a food equal to breast milk. Mothers should nurse their babies for at least six months. Many mothers wean babies early on the advice of careless physicians. By mixed feeding is meant the substitution of one or more breast feedings daily by some other food. There are two reasons for mixed feeding: 1. When the mother's health is impaired, or she is suffering from loss of weight or anemia. 2. When the baby fails to thrive, does not sleep well, or has indigestion frequently. Mixed feeding is better and safer than artificial feeding. Teachers should instruct students as to the importance of mixed feeding. Careless weaning often means loss of life, while a combination of bottle and breast feeding in many cases will save the baby's life. The laity should be educated on the subject of mixed feeding.

What Shall We Teach Concerning the Feeding of Difficult Cases?

Dr. G. R. Pisek, New York: We meet with two classes of difficult cases: 1. Infants that are healthy at birth but that develop digestive disturbances after being breast fed. 2. Babies that do not thrive from the first. Teach the student the value of foods and the physical and chemical properties of milk. The student should be taught how to prepare the milk formulæ and he should likewise be taught the elementary laws of biology. Any form of food that agrees may be used as a starting point. Study the individual needs of the infant and gradually work up to a formula that will meet the particular requirements.

Discussion on Infant Feeding

Dr. J. W. Van Derslice, Chicago: As soon as we eliminate methods so soon will we get results in these feeding cases. We must stop teaching methods and teach infant feeding. This ought to be our next step. In regard to mixed feeding, I prefer the admixture of cow's milk and mother's milk to giving the child table foods.

Dr. A. C. Cotton, Chicago: Mixed feeding does good when mother's milk fails. It is a mistake to recommend the bottle in all cases except where there is a contraindication to breast feeding. Breast-fed babies have dyspepsia which is not always due to improper feeding but rather due to bad mother's milk.

Dr. I. L. Poloske, Detroit: Teach the obstetrician not to recommend early weaning and early recourse to the bottle. He is usually in charge of the case for the first few weeks and can be a power for much good in this direction. As soon as you advocate bottle feeding as a substitute for breast feeding you lessen stimulation to the breast and hence there is less breast milk.

AMERICAN ORTHOPEDIC ASSOCIATION

Twenty-second Annual Meeting, held at Hartford, Conn., June 14-16, 1909

(Continued from page 479)

Method of Anchoring Transplanted Tendons

Dr. S. L. McCurdy, Pittsburg, described his method as consisting in wrapping the tendon entirely around the bone, passing it through the ligament, or securing it to some dense or firm tissue, rather than in simply suturing it to the periosteum, thus guaranteeing a firm anchorage after union.

DISCUSSION

Dr. Rugh: I can testify to the value of this method. I think that the less one disturbs the bone from its position the less one will interfere with nutrition and the more quickly there will be union. Formerly I sawed off the ends of the bone squarely, but now I simply saw one side, and then go in through the other way. I have also used the method of having a hole through the end of the drill, as well as the wooden screws. I have never had any harm result from using silver wire.

Dr. Wilson: I think that many of the objections to silver wire lie in the quality of the metal used. Iron always produces irritation by corroding and requires removal in a few weeks.

Dr. McCurdy: I have been taking x-ray pictures from time to time, and I find that the shadow cast by the wire is growing less, showing that it is being disintegrated and will gradually disappear.

Unusual Cases of Caries of the Spine in Adults

Dr. E. G. Brackett, Boston, considered some of the special features of this condition and the etiology of some of the spinal symptoms. He also made an attempt to classify them

Book Notices

TEXT-BOOK OF EMBRYOLOGY. By Frederick Randolph Bailey, A.M., M.D., Adjunct Professor of Histology and Embryology, College of Physicians and Surgeons (Med. Dept. Columbia Univ.) and Adam Marion Miller, A.M., Instructor in Histology and Embryology, College of Physicians and Surgeons (Med. Dept. Columbia Univ.). Cloth. Pp. 672, with illustrations. Price, $4.50. New York: William Wood & Co., 1909.

This book, while including subjects of interest to the general student of embryology, is primarily intended "to present to the student of medicine the most important facts of development, at the same time emphasizing those features which bear directly on other branches of medicine." It is accordingly divided into two parts and an appendix. Part I deals with general development. Part II with the development of the adult tissues and organs. To each chapter there is appended a good bibliography and "practical suggestions" for laboratory work, embracing the subjects dealt with in that chapter. In each chapter of Part II there is added under "anomalies" an embryologic consideration of malformations peculiar to the structures taken up in the respective chapter. There is also a special chapter on teratogenesis in which are discussed duplicity of structures and fetus, defects in fetus and the causes underlying the origin of monsters.

Part I includes a discussion of the cell, mitosis, the male and female, sex cells, maturation, fertilization, cleavage, the germ layers, the fetal membranes and the development of the external form of the body. While this is primarily a text-book of human embryology, yet, owing to the scarcity of early human embryonic material, early development as seen in the lower forms is of necessity resorted to. The simpler types of development, such as that of the Amphioxus, the chick and the frog constitute the basis for the consideration of the development of the germ layers. It is to be regretted that Chapter V (cleavage) and Chapter VI (the germ layers) do not compare favorably with the remainder of the book. These subjects form almost the entire basis for the field of embryology, and any inadequacy or errors in this part of a text-book are particularly serious.

Part II embraces the development of the connective tissue, the skeletal, muscular, vascular, respiratory, circulatory, urogenital, integumentary, and nervous systems, the alimentary tube and appended organs, the organs of special sense, and teratogenesis, and is a decided improvement over Part I. This is especially true of Chapter XVII (the nervous system), which is the best part of the book. Here a very difficult subject is treated in a comprehensive yet lucid manner, which places it easily within the grasp of the average medical student. One would naturally expect to find the name of the author of this chapter (Dr. Oliver S. Strong) on the title-page. The nervous system covers practically one-fifth of the book, yet Dr. Strong is only slightly mentioned in the preface. The development of the vascular system (Chapter X) is also well brought out.

There are 515 illustrations in the text. In Part II they are in the main good, well selected, and compare favorably with those of the best English text-books of embryology. The general plan of the book is an excellent one. but is perhaps better suited to a more extensive work on the subject. It is doubted if sufficient time can be spared from an already well-crowded curriculum to cover the subject of embryology as outlined in this text. One would think that the authors, in writing a general text for medical students, had shown a slight tendency to place it beyond their grasp; since an adequate knowledge of the great variety of subjects dealt with and of such subjects as teratogenesis and the causes underlying the origin of monsters, can not be obtained from so brief a text. A great deal of supplementing by lectures and original articles would be required, which would require more time than can be ordinarily devoted to the subject. The book is well printed. Several technical errors (due probably to oversight) and apparent contradictions in Part I will doubtless be corrected in the first revision of the book.

THE ERRORS OF MIND-HEALING. By Reinhold Willman, M.D., St. Joseph, Mo. Cloth. Pp. 179. Price, $1. St. Joseph, Mo.: The Advocate Publishing Co.

Dr. Willman, with the praiseworthy intention of setting forth, as he says, the view that the physician can and must take of the Scriptural records of miracles, argues to show that there is nothing in common between those miracles and the modern use of hypnotism, suggestion, faith healing, etc. Accepting the accuracy of the records, which a believer in Christianity is obliged to do, he seems to us to be on the right track. There are some clergymen and critics who attempt to reconcile the New Testament miracles with modern science and account for them as far as they can by known phenomena. Dr. Willman shows the fallacy of this and makes it clear that their only alternative to accepting the Biblical statements is to doubt the records. In the latter part of his book he takes up modern faith healing, Eddyism, Dowieism, etc., and shows up the commercial spirit that underlies nearly all of them. We wish he could have had his book revised to free it from certain slips in the author's English as well as numerous typographical errors. His quotations from Mrs. Eddy's "Science and Health" and the text-books of Emmanuelism are rather apt in support of his argument.

THE GREATEST GOOD OF MANKIND: PHYSICAL OR SPIRITUAL LIFE. By William Wenzlick, LL.B., M.D. Cloth. Pp. 374. Price, $1.50 net. Chicago: Published by the Author, 1206 Lawrence Ave.

This book is made up of alternate opposed views in regard to questions of sociology, religion, etc., by two supposed writers, Dr. Fact and the Reverend Faith. Dr. Fact, the materialist, critic of the Bible after Tom Paine, and opponent of prohibition, represents Dr. Wenzlick's sentiments, while the Reverend Faith is a severe specimen of the cloth and not at all such a lovable representative of religion as its friends would prefer to have speak in refutation of the scoffer's sophistries. This method of setting up a man of straw or arguing with a dummy is a convenient one because the disputant has in it altogether his own way. We very much doubt its effectiveness in argument, however. Dr. Wenzlick has evidently done a large amount of reading of the Scriptures, but in a very critical and hostile spirit, which would probably give offense to a large majority of the reading public if his book were so fortunate as to come under their notice. In fact, a large proportion, we believe, of those who agree with him more or less in his ideas of personal liberty, so-called, would take offense at his sentiments in some other lines. His estimate of the value of alcohol and the blessing of the saloon will not be shared by the majority of conservative physicians.

Society Proceedings

ASSOCIATION OF AMERICAN TEACHERS OF THE DISEASES OF CHILDREN

Third Annual Meeting, held at Atlantic City, June 7, 1909

(Concluded from page 477)

Personal Relations of Teacher and Student

DR. EDWARD J. WYNKOOP, Syracuse, N. Y.: In many colleges, pediatrics is taught only in the fourth year. It is a most important subject for the young practitioner, inasmuch as two-thirds of his practice during the first few years will consist of accidents and diseases occurring among children. Only by the institution of more clinical work in the college can we hope to come in more personal contact with the student. The identity of the individual student is not always known. A personal knowledge of each man should be insisted on. The classes should be divided into sections of ten men each so as to establish personal relationship with each man. Teachers in medical colleges should take more interest in the social side of the student's life, and teachers should likewise bear in mind that they owe the student something more than merely classroom instruction.

DISCUSSION

DR. A. C. COTTON, Chicago: The tendency to-day is toward larger teaching faculties so as to bring the students in touch with the subject in smaller classes. The teacher has an opportunity, therefore, of studying the actual needs of the individual student. The large staffs of the hospitals connected with our colleges enable the assistants to report to the chief of the staff the needs of the various students. Frequent quizzes, and the visiting of the staff by the students, partly fills the void created by the departed preceptor who was so valuable in olden times.

Dr. A. Jacobi, New York City: The only place to teach medicine is at the bedside of the patient, or, if the college has a hospital connection, from material secured from the outpatient department. Unfortunately, most of our medical schools have no hospitals. We have too many students, or, perhaps, we have too many colleges. Large schools with large hospitals require a large teaching staff, and the aim of the teacher should be first, to secure suitable material for instructing the students, and, second, to divide the classes into sections of ten or twelve men each, so as to impart almost individual instruction.

Report of the Committee on the Teaching of Pediatrics

Dr. S. W. Kelley, Cleveland: Each college should have a chair of pediatrics with full professorship. Pediatrics should be studied in the junior and senior years. The course should be graded and include the anatomy and physiology of infancy and all the affections of childhood both medical and surgical. The surgical side of pediatrics may be taught in the chair of surgery. A large part of the teaching should be clinical. The classes should be divided into sections of ten or twelve men. No college without a hospital or dispensary for children is prepared to successfully teach diseases of children.

How Should the Percentage Method of Milk Modification be Taught?

Dr. J. Finley Bell, Englewood, N. J.: The chemical and physical constituents of cow's milk as compared to those of mother's milk are so different that the percentage method as taught to-day does not solve the problem of milk modification. The proteid and fat percentages are at fault. The student in college should be taught how to examine specimens of milk. We should teach general principles only, permitting the student to form his own conclusions. The universal adoption of the metric system will simplify the matter and render the results more accurate. In preparing the formulas a knowledge of the physiologic needs of the infant is necessary.

What Should Be Taught Concerning Proprietary Foods and Condensed Milk?

Dr. I. L. Poloske, Detroit: The students in our colleges should be taught the difference between cow's milk and proprietary foods. Proprietary foods are deficient in fat and have an excess of carbohydrates. Condensed milk and proprietary foods predispose the baby to scurvy, rickets, constipation and the various infectious diseases. All proprietary foods are rich in flour and dextrin. The physician must know the value of the food he prescribes and with patented foods this is impossible. Condensed milk should be used in catarrhal diseases where cow's milk can not be used. The enormous number of proprietary foods on the market is due to the large number of physicians who prescribe them.

DISCUSSION

Dr. H. M. McClanahan, Omaha: There are two reasons why proprietary foods are used: 1. They are advertised directly in the home. 2. A large percentage of the profession is indifferent as to the methods of milk modification. It is a very good plan to warn students regarding the harmful effect of these patented foods.

What Should Be Taught About Mixed Feeding?

Dr. H. M. McClanahan, Omaha: Science and art can not prepare a food equal to breast milk. Mothers should nurse their babies for at least six months. Many mothers wean babies early on the advice of careless physicians. By mixed feeding is meant the substitution of one or more breast feedings daily by some other food. There are two reasons for mixed feeding: 1. When the mother's health is impaired, or she is suffering from loss of weight or anemia. 2. When the baby fails to thrive, does not sleep well, or has indigestion frequently. Mixed feeding is better and safer than artificial feeding. Teachers should instruct students as to the importance of mixed feeding. Careless weaning often means loss of life, while a combination of bottle and breast feeding in many cases will save the baby's life. The laity should be educated on the subject of mixed feeding.

What Shall We Teach Concerning the Feeding of Difficult Cases?

Dr. G. R. Pisek, New York: We meet with two classes of difficult cases: 1. Infants that are healthy at birth but that develop digestive disturbances after being breast fed. 2. Babies that do not thrive from the first. Teach the student the value of foods and the physical and chemical properties of milk. The student should be taught how to prepare the milk formulæ and he should likewise be taught the elementary laws of biology. Any form of food that agrees may be used as a starting point. Study the individual needs of the infant and gradually work up to a formula that will meet the particular requirements.

Discussion on Infant Feeding

Dr. J. W. Van Derslice, Chicago: As soon as we eliminate methods so soon will we get results in these feeding cases. We must stop teaching methods and teach infant feeding. This ought to be our next step. In regard to mixed feeding, I prefer the admixture of cow's milk and mother's milk to giving the child table foods.

Dr. A. C. Cotton, Chicago: Mixed feeding does good when mother's milk fails. It is a mistake to recommend the bottle in all cases except where there is a contraindication to breast feeding. Breast-fed babies have dyspepsia which is not always due to improper feeding but rather due to bad mother's milk.

Dr. I. L. Poloske, Detroit: Teach the obstetrician not to recommend early weaning and early recourse to the bottle. He is usually in charge of the case for the first few weeks and can be a power for much good in this direction. As soon as you advocate bottle feeding as a substitute for breast feeding you lessen stimulation to the breast and hence there is less breast milk.

AMERICAN ORTHOPEDIC ASSOCIATION

Twenty-second Annual Meeting, held at Hartford, Conn., June 14-16, 1909

(Continued from page 479)

Method of Anchoring Transplanted Tendons

Dr. S. L. McCurdy, Pittsburg, described his method as consisting in wrapping the tendon entirely around the bone, passing it through the ligament, or securing it to some dense or firm tissue, rather than in simply suturing it to the periosteum, thus guaranteeing a firm anchorage after union.

DISCUSSION

Dr. Rugh: I can testify to the value of this method. I think that the less one disturbs the bone from its position the less one will interfere with nutrition and the more quickly there will be union. Formerly I sawed off the ends of the bone squarely, but now I simply saw one side, and then go in through the other way. I have also used the method of having a hole through the end of the drill, as well as the wooden screws. I have never had any harm result from using silver wire.

Dr. Wilson: I think that many of the objections to silver wire lie in the quality of the metal used. Iron always produces irritation by corroding and requires removal in a few weeks.

Dr. McCurdy: I have been taking *x*-ray pictures from time to time, and I find that the shadow cast by the wire is growing less, showing that it is being disintegrated and will gradually disappear.

Unusual Cases of Caries of the Spine in Adults

Dr. E. G. Brackett, Boston, considered some of the special features of this condition and the etiology of some of the spinal symptoms. He also made an attempt to classify them into various types for the purpose of study, with reference to a possibly more accurate diagnosis of the location of the part of the vertebra affected.

DISCUSSION

Dr. Clarence L. Starr, Toronto: The picture representing the vertebræ broken down brings to my mind the case of a child that I had under treatment for three years on a Whitman frame in hyperextension. She died of miliary tuberculosis, and the specimen showed no attempt at fusion. This impressed on me that by continued hyperextension we may prevent the fusion of the bones, and that if we succeed it must be by a prolonged treatment with apparatus.

Dr. A. Thorndike: These studies bring out the fact that the process of bony union takes place late in Pott's disease. Until the tuberculous process dies out the bony process will not begin.

Dr. H. L. Taylor: We should be careful about diagnosing spinal neurasthenia until we have excluded with certainty caries of the vertebræ.

Dr. C. Riely: I think that the long duration of the disease in adults without deformity is due to the great amount of mineral salts in them as compared with children.

An Operation for Infantile Cerebral Hemiplegia, With Reports of Two Cases

Dr. Joseph John Nutt, New York, had devised this operation to give prolonged rest to the lower neurons and thereby rest the upper neurons on the hypothesis that the destruction of cerebral tissue due directly to the original lesion was small in comparison with the total area involved. The rest and repair of certain cells directly by the operation should influence indirectly the rest and repair of others.

DISCUSSION

Dr. Cook: How long do you think the interval would be before the nerve grew together again?

Dr. J. J. Nutt: I did not find much information about this in the literature. In one case it was about nine months.

Dr. Rugh: Have there been any beneficial effects in cases of paraplegia or in the diplegic forms of spastic paralysis, and was sensation entirely done away with when motion was arrested?

Dr. J. J. Nutt: Sensation in the small sciatic was entirely paralyzed. A great many cases of diplegia were reported in which more improvement was noted than one would expect from simple tenotomy.

Dr. Baer: In cases of anterior poliomyelitis, in which I tried nerve severing, the effort was to see whether division of the sciatic nerve and the twisting of the nerve on itself would let the neurons spread out and go down the bad paths into the distal portion of the nerve, as well as the good, but the neuron selected the path it had originally gone down.

Dr. Myers: When did the lesion occur?

Dr. J. J. Nutt: The patient was three years old when it occurred and is now thirteen.

Dr. Blodgett: Has the mentality improved?

Dr. Nutt: The nurse tells me she has noticed some.

Dr. E. R. Fisher, New York: In this class of cases we have a condition that can be relieved, but not cured. There is no inflammatory condition, but an irregular cell action, or overaction. By the removal of this sensory irritation the cortex is given a chance to rest. For the time being the muscle is paralyzed, and this gives an opportunity to apply treatment to the opposing muscle, which is weaker than the contracted or spastic muscle. I do not believe that we can expect a return of mental power except in young cases.

Dr. E. Ryerson, Chicago: I have obtained good results by transplanting the hamstrings forward into the patella, the children learning to walk in a year and a half. For the children who are entirely idiotic nothing can be done mentally; for the others a great deal can.

Dr. Bradford: I should like to know whether the injection of curare has been tried to paralyze the nerve.

Dr. Fisher: I have a faint recollection that this was alluded to in a discussion at the last meeting of the American Neurological Association, but that it was not successful.

Physicians as Witnesses When They Have Not Treated Injured Parties

The Supreme Court of Illinois says, in the personal injury case of Fuhry vs. Chicago City Railway Co., that a physician who has not treated the injured person, but has made an examination to enable him to testify on a trial as to his condition, must base his opinion on objective, and not subjective conditions. He can not relate nor take into consideration the self-serving statements of the injured person made to him, not with reference to his treatment, but with reference to his trial.

With regard to a question asked a physician the object of which was to obtain his opinion as to whether a certain condition could, would, or did result from certain injuries, the court says that the question whether it did so result was for the jury to determine, but, being one not within the knowledge of men of ordinary experience, the opinions of physicians having knowledge of that subject were proper to be considered and did not invade the province of the jury. It was immaterial whether the witness testified that the injury might or could cause the condition or that it did cause it. In any event the testimony was merely the opinion of the witness based on the facts he had testified to. It was still for the jury to determine the truth in regard to those assumed facts, as well as any others which might tend to confirm or modify their reliance on the opinion given.

Life Tables with Reference to Person Engaged in Hazardous Business

The Court of Appeals of Kentucky says, in Louisville & Nashville Railroad Co. vs. McMillen, a personal injury case brought by the latter party, that life tables were properly allowed to be given in evidence to show the plaintiff's expectancy of life. The fact that he was in a hazardous business, and that the tables were based on the expectancy of life of persons in ordinary occupations, should be taken into consideration by the jury; but, after all, the tables were some evidence of the probable duration of life, and perhaps the best evidence that could be obtained on the subject. There was no presumption that he would continue in a dangerous business. His employment might be ended at any time, and so this was only a circumstance to be considered by the jury in determining what weight to give to the life tables.

Cross-Examination as to Frequency of Experts Appearing as Witnesses

The Supreme Court of Illinois says, in the case of McMahon vs. Chicago City Railway Co., where a physician was cross-examined as to how many cases he had testified in as an expert for the street car lines of Chicago, that the extent of an examination along this line is largely within the discretion of the trial court. No definite limit can be prescribed as a rule of law. The weight to be accorded to the opinion of an expert witness depends largely on his means of information and knowledge, as well as his bias and inclination or relation to the parties. It is always competent to show the interest of the witness. The court thinks, however, that the question should have been limited to the number of times the witness had testified for the defendant company.

Alcoholic Medicinal Preparations

Robert Williams, Jr., acting commissioner, states that it is the practice of the office of commissioner of internal revenue, where preparations examined by it are found to be clearly and unmistakably fakes, being chiefly composed of whisky with little or no medication, and where the character of the preparation must be known to the druggist handling same, either by reason of its appearance or by the nature of the demand for it, to require special tax for its sale without any previous notice being given.

This office holds that in a genuine medicine the alcohol should not be more than is necessary for the legitimate purposes of extraction, solution, or preservation, and that the preparation should contain approximately a U. S. P. dose of some medicinal ingredient of recognized value, either alone or in combination with other compatible drugs. Where a substantial effort has been made to introduce medication, without, however, coming up to the standard set by this office, it is the practice to notify the manufacturers and give them an opportunity to change their formulas; and in such cases, while the manufacturer is required to pay special tax on account of the manufacture and sale by himself of such preparations, special tax is not required of retail druggists on account of the sale of the same in good faith for medicinal use only, if the formula is changed, or until after public notice has been given, if the manufacturer declines to make such change.

6 The General Practitioner as a Dermatologist. B. F. Ochs, New York.

1. **Parasitism and Natural Selection.**—Eccles says that when we study the distribution of parasites in time and place, we find them such as would be a source of stimulation of germplasm, such as is required in a world that is biologically what we live in. Disease may thus yet prove to be a blessing instead of a curse. Ineffective disease in vertebrate and invertebrate animals is a contest of cells with cells, protozoan and protophyton against metazoon for food. Many of the pathogenic micro-organisms discovered infest insects, molluses, fishes and amphibians.

Parasitism is as old as the world, and is found in fossil remains millions of years old; it is hereditary. The sporozoa are entirely parasitic, one form inhabiting the spleen, another the liver and gall-bladder, etc. These parasites have become so specialized that some of them can live only in certain structures and higher forms of animal life. Parasite and host have learned how to repel each other's attacks, the one by secreting special enzymes to dissolve envelopes, the other by the formation of antibodies to hold poisons in abeyance. Immunity is a gaining of structural and poisonous protection through generations of struggle. Disease is an important part of the biotic fight for food and an essential part of the theory of natural selection. Survival and fitness are due to a triumph over disease. There is no other factor so universally present. The first requisite in this struggle is health, and this is possible only among organisms whose progenitors have triumphed over disease, the weaklings having all been destroyed. Climate and isolation predispose to disease, to variation, but neither alone is an efficient cause of variation. Evolution is brought about by the introduction of the abnormal. The nearer we get to the germ-plasm the easier it is to produce changes in adult forms. All organic changes are the result of stimuli, and disease is the greatest form of stimulus.

4. **American School of Tropical Medicine.**—Brewer says that the sanitary administration of our new tropical possessions demand medical officers acquainted with the diseases peculiar to the tropics. The teaching in medical schools gives no knowledge of tropical diseases, and even if such were given there would be no clinical material. There should be established in this country a school of tropical medicine and attached to it should be a hospital in which the needed clinical material should be collected.

8. **Injections of Sea Water in Skin Disease.**—Sea water contains the chlorids of sodium, magnesium, calcium and potassium, and the sulphate of magnesium. These salts have different and opposite effects, i. e., sodium chlorid is a stimulant to nerves and muscles, while the magnesium, calcium and potassium salts are inhibitory in their actions. Mayer describes these opposing forces in the case of one of the medusæ whose pulsations are produced by the electrical (?) energy generated, as in a battery, by the action of these various salts.

With this phenomenon as a basis for the possible therapeutic power of sea water the following experiments were undertaken by White: The water was obtained from the ocean about thirty miles south of Woods Hole, Mass., and from a depth of thirty feet, thus insuring a pure, uncontaminated supply. This water was placed in sterile jars and brought to Boston, where it was purified by passing through a Chamberland filter and rendered isotonic with blood serum by the addition of sterile tap water in the proportion of ten parts of the former to twenty-three of the latter. This product was placed in sterile glass ampullæ holding 200 c.c. One end of these receptacles was bent in the form of a hook and the other drawn out into a straight line, and both extremities were sealed.

The injections were made three times a week deep into the buttocks of the patient, who lay on his side and allowed the fluid to run into the tissues by the force of gravity, the ampulla being suspended about three feet above the body and the water passing through a sterile rubber tube and long irido-platinum needle. The rapidity of the injections varied a great deal in the different patients, some requiring at least a half hour to take in 150 c.c. The pain and discomfort attending this maneuver was usually very slight and the only immediate effect was the desire to urinate; while the general after-effects were practically *nil*, although one patient was obliged to take to her bed for twenty-four hours twice on account of chills, fever, lassitude and nausea.

The following cases were so treated: Pemphigus foliaceus; scrofuloderma; psoriasis; eczema seborrhoicum; malingering, varicose ulcers and general fibromatosis; lupus vulgaris (two cases); erythema induration and psoriasis; chronic eczema (three cases); lupus vulgaris and scrofuloderma; scrofuloderma and xeroderma. From the study of these fifteen cases treated by the injections of isotonic sea water, certain conclusions may be drawn:

> 1. This unusual therapeutic measure produces a certain amelioration of symptoms in widely various dermatoses. 2. This improved condition is most conspicuous in tuberculous processes, especially in tuberculous ulcers. 3. As a whole, this therapeutic agent is a great disappointment. 4. Sea water can be injected in surprisingly large amounts, even into children, without causing much pain or other untoward symptoms. 5. Sea water injected into the buttocks causes immediate desire to micturate, a continued easy and sometimes increased number of daily movements of the bowels, as a rule a slight tendency toward increase of bodily weight, and at times a distinct improvement in the well-being of the recipient.

9. **Psychoses in Puerperal State.**—Ricksher says that there is no psychosis which can be strictly called a puerperal psychosis, but there is no doubt that the puerperal states can act as an exciting cause of a psychosis in certain women under certain conditions, which conditions are at present unknown. The mortality of children born of mothers who become insane during pregnancy is very great. The puerperal states may be exciting causes of attacks of manic-depressive insanity in women who have never before been insane, and in women who have had previous attacks of this disease, childbearing is apt to be the exciting cause of another attack. In women suffering from dementia præcox the puerperal states cause an exacerbation of the acute symptoms and cause the psychosis to become more active.

Homicide is comparatively rare among women becoming insane during this period and is more liable to occur in patients suffering from dementia præcox than any other psychosis, while attempts at suicide are less numerous in these cases but are more liable to occur in patients suffering from the depressed form of manic-depressive insanity. Eclampsia and the toxic infections are not more frequent in women who become insane than in women who are normal mentally and these factors are of little moment in any but the toxic deliria. Illegitimate children are not given as the cause of insanity as frequently in this country as in Europe. The reason for this is not determined. Comparatively few women who later become insane show abnormalities in pregnancy, and one can not tell from the character of the pregnancy whether a woman will become insane after labor or during lactation.

15. **Leucocytes and Differential Count.**—Coons and Bratton report 184 cases of acute appendicitis in which the blood examination was made a few hours previous to operation, except in a few instances in which the patient died before operation or there was a delay for some reason. Following a scheme of Noehren, of New York, the cases were divided into five groups: 1, acute suppurative appendicitis, inflammation confined to appendix; 2, gangrene; 3, abscess; 4, perforation, local peritonitis; 5, spreading peritonitis—the infection not confined by adhesions; 6, general peritonitis. Of the cases of acute suppurative appendicitis, twenty-six out of forty-one had a polynuclear count between 80 and 90; in one instance the polynuclears were 91 per cent. The leucocytes varied between 10,000 and 20,000 in thirty-four of the forty-one cases. In cases with abscess, thirty out of the sixty-two cases had polynuclears from 80 to 85 per cent. There were seventeen cases below 80 per cent.; thirteen, from 85 to 90 per cent.; two, above 90 per cent.

Of twenty-two cases of gangrene, ten had from 85 to 90 per cent. polynuclears. The leucocytes in no instance ran above 25,000; in four cases the white cells were not increased. Of the cases of perforation with local peritonitis, and spreading peritonitis, thirty-six out of forty-five cases showed polynuclears between 85 and 95 per cent. The leucocytes ranged, irregularly, from 10,000 to 49,000. Four cases with very high total leucocyte counts were found. One case with perforation, 40,000 and 91 per cent. The second, an abscess, with 40,300 and 89.3 per cent. The third, a case with free pus in the abdomen, not walled off by adhesions, 40,000 leucocytes, 89.9 per cent. polynuclears. The fourth, a case of spreading peritonitis, with 49,000 leucocytes and 85.6 per cent. polynuclears. The body resistance in these cases, as indicated by the high total leucocyte count, was unusually good, while the degree of infection, revealed by the percentage of polynuclears, was rather mild. These patients had a plus resistance or a falling line. They make good recoveries. The authors summarize their findings as follows:

Polynuclears below 75 per cent.: If there is a leucocytosis, one may look for an old infection, well walled off, may be an acute exacerbation. Usually there is a mild secondary anemia.

Polynuclears, from 75 to 80 per cent.: Indefinite; the history of the case and the patient should be considered. In our series
from 75 to 80 per cent.; 15 were ab-
appendicitis.
85 per cent.: The patient is in no
total leucocyte count is low, suggesting a poor resistance. If the leucocytes are increasing, an immediate operation should be advised if the relation of the polynuclears to the total leucocyte count indicates a good resistance. If the leucocytes remain stationary or decline, the surgeon should rely on the physical signs in making up his mind when to operate.

Polynuclears, from 85 to 90 per cent.: Look for a severe infection. If there is a proper leucocytosis, according to the chart, an immediate operation is indicated.

Polynuclears, above 90 per cent.: Virulent infection, grave prognosis. Twenty-five of our 31 cases above 90 per cent. had some form of peritonitis. Where there is no increase in the leucocytes, and the polynuclears high, little hope can be entertained for the patient from an operation.

17. **Common American Foods.**—Greenbaum has calculated the fuel value (calories) of a certain number of American foods per ounce (avoirdupois), utilizing almost entirely the results obtained by the United States Department of Agriculture, and in particular Bulletin No. 28 (revised edition), by W. O. Atwater and A. P. Bryant. He also submitted a few sample diets for patients suffering from obesity, which can easily be modified to the individual needs by utilizing his table. Personally, he prefers to use six meals a day, the usual breakfast, luncheon and dinner, with three small feedings between them. This has the advantage of preventing undue weakness and excessive desire for food at the main meals.

18. **Treatment of Epistaxis.**—Robinson favors plugging the nasal passages by taking a strip of aseptic, absorbent cotton, and twisting it round and round, so that it becomes about the size of the little finger, and then with a good light, a nasal speculum, and a director or stiff probe, fill the lower and middle meatus as far back as the posterior pharynx. After twenty-four or forty-eight hours the plug or plugs begin to loosen by reason of the nasal secretions produced and absorbed, and they should be carefully withdrawn and fresh ones substituted, if necessary.

24. **Calcium Salts in Gastric Tetany.**—The case reported by Kinnicutt is of interest in view of the rarity of that form of gastric tetany associated with dilatation of the stomach and stagnation of its contents, of which it is an example; in the severity of the tetanic symptoms, and in the prompt inhibitory effect on the spasms of the calcium salts artificially introduced directly into the blood stream. It was found impossible to nourish the patient by means of the stomach. Vomiting was frequent on each attempt, in spite of copious and frequent lavage. Nutriment introduced after lavage by means of the stomach tube, although sometimes retained, was recovered later by the tube in like amounts, showing no signs of gastric digestion—only decomposition processes. Nutrient enemas were retained only exceptionally. There was almost complete anuria for the first twenty-four hours and until abundant subcutaneous clyses of salt solution had been given. Later the urine either was voided involuntarily or was recovered by catheterization. The scanty fluid stools were mostly involuntary. Although the tetanic symptoms obviously could be con-

trolled by the continued administration of the calcium salts, it was equally apparent that the patient would slowly die of inanition unless the evident gastric stenosis could be relieved by operation. Surgical intervention was decided against on the ground that any operation would be immediately fatal. The patient died suddenly.

Certain facts stand out prominently in the clinical study of the case: 1. The rapid and controlling effect of the soluble calcium salts on the tetanic symptoms. 2. The maintenance of this effect only by their continued use. 3. The comparatively slight effect of large infusions of salt solution, used alone. 4. The slight influence, if any, of parathyroid preparations (nucleoproteid) given by the mouth in controlling the hyperexcitability of the nervous system. The demonstration of the controlling influence of the soluble calcium on the characteristic symptoms of at least one important variety of human spontaneous tetany—the tetany of gastrectasis, with stagnating stomach contents—suggests a probable similar therapeutic value of these salts in other forms of the disease in human beings. The occurrence of typical tetanic spasm in a case of gastrectasis with parathyroid bodies of normal anatomic structure—and presumably—of normal functioning power.

25. **First Sound of Normal Heart.**—Sewall directs attention to a modification of the first sound of the heart which allies it qualitatively to the first sound as heard in mitral stenosis, but which predicates no organic lesion. In the structurally normal heart, especially in conditions of circulation excitement, the first sound frequently begins with the crescendo tone, simulating closely the faint and brief presystolic murmur or acute accent initiating the first sound in certain stages of organic mitral stenosis. The modification of the first sound may be pronounced either in the tricuspid or the mitral area, or both.

28. This will be abstracted later in the Department of Therapeutics.

33. **Tuberculous Pulmonary Cavities.**—White and Carpenter claim that cavity formation does not occur with the same frequency in infants as in older children. In their own autopsies, 16 per cent. of the infants dead from tuberculosis showed cavity formation; a far lower percentage than is reported by other observers. The infants usually succumb to the widespread process before the larger lesions have time to soften and their contents to be thrown off. In the author's cases tuberculous cavities in infants occurred most often at the root of the lungs, in the middle and lower lobes.

35. **Fatal Anemia of Unknown Cause.**—The cells described by Barker are large, rounded, or oval, with from one to three vesicular neutrophilic nuclei and pale basophilic protoplasm; in the protoplasm there is more or less coarse granular material staining a deep red; in some of the cells this material takes the shape of straight or slightly curved rods, some of them beaded. That these rods were not artefacts was proved by their appearance in many smears. They are similar to rods seen in the protoplasm of lymphocytes in a case of acute lymphatic leukemia reported by Auer, but the cells are not lymphocytes, nor prelymphocytes. They are obviously young cells, many of them in active division, but none of them show evidence of phagocytic activity. Barker's case is reported partly because of the rarity of fatal anemia in early childhood similar to the "pernicious" anemia of adult life, and partly to place on record the appearance of the cells described.

48 Continuous Respiration Without Respiratory Movements. S. J. Meltzer and J. Auer, New York.

41. **Blood Platelet and Megalokaryocyte Reactions.**—The platelets in the circulating blood are of uniform structure and of common origin. The curve of regeneration after destruction or loss is independent of those of regeneration of red corpuscles and of leucocytes, but at the same time as or preceding the increase in the number of platelets in the blood stream the megalokaryocytes of the bone marrow are increased in number. Bunting corroborates the discovery of J. H. Wright that the blood platelets are formed by segmentation of portions of pseudopodia separating from the megalokaryocytes.

43. **Hemorrhagic Necrosis of Pancreas.**—Hemorrhagic pancreatitis, so-called, is in reality primarily a necrosis of the parenchyma of the pancreas and should be called hemorrhagic necrosis, the inflammatory changes present being secondary to the necrosis or subsequent to infection. The so-called pancreatic apoplexy is the result of acute necrosis of the pancreas. In some cases necrosis may lead to little or no hemorrhage. "Gangrenous pancreatitis" is a late stage of hemorrhagic necrosis, a most frequent cause of which, in man, is the entrance of irritating material into the ducts of the pancreas, such as bile diverted by a gallstone lodged at the duodenal orifice of the common duct. Duodenal contents entering the duct may have the same effect, and in a small proportion of cases necrosis may follow injury of the pancreas, being in this case probably in part referable to simultaneous thrombosis. Anatomic peculiarities or anomalies of the pancreatic ducts may predispose to hemorrhagic necrosis.

44. **Strains of Diplococci in Meningitis.**—No reliable points of difference were found between strains of *Diplococcus intracellularis* from typical cases of epidemic meningitis, and several strains of cocci obtained from cases of posterior basic meningitis. With diplococci obtained from posterior basic meningitis acutely fatal meningitis was produced in monkeys. Consequently antimeningitis serum should be used in case of posterior basic meningitis.

46. **Butyric Acid Test in Syphilis.**—The cerebrospinal fluid in syphilitic individuals, like the blood serum, contains more globulin, and especially euglobulin, than normally. By virtue of this increase the following butyric acid reaction is applicable to the diagnosis of syphilis: One or two parts of spinal fluid are mixed with five parts of 10 per cent. butyric acid solution and heated over a flame to a brief boiling. One part of normal solution of sodium hydroxid is then added quickly to the heated mixture and the whole is boiled once more for a few seconds. The presence of an increased content of protein in the spinal fluid is indicated by the appearance of a granular or flocculent precipitate which gradually settles under a clear supernatant liquid. The granular appearance of the precipitate is held to be a positive reaction for syphilis or parasyphilitic affections. It was found that in the second or third stages of syphilis without direct involvement of the nervous system the cerebrospinal fluid gave the butyric reaction feebly and under these conditions the fluid did not give the Wassermann test nor a positive cell count according to the method of Rabaut; in hereditary syphilis a positive butyric reaction was obtained in 90 per cent. and a positive Wassermann in about 80 per cent of the cases examined; in the cases of cerebral and spinal syphilis examined every one gave the butyric reaction and the cell count, the Wassermann reaction being obtained in from 50 per cent. to 75 per cent.; the cases of general paralysis gave positive butyric reaction in 90 per cent., positive cell counts in 91 per cent., and positive Wassermann in 73 per cent.; in cases of tabes, the cerebrospinal fluid gave a positive butyric reaction and cell count in 100 per cent., and a positive Wassermann in 53 per cent. From these and other facts it is concluded that the butyric

Homicide is comparatively rare among women becoming insane during this period and is more liable to occur in patients suffering from dementia præcox than any other psychosis, while attempts at suicide are less numerous in these cases but are more liable to occur in patients suffering from the depressed form of manic-depressive insanity. 48 Continuous Respiration Without Respiratory Movements. S. J. Meltzer and J. Auer, New York.

41. **Blood Platelet and Megalokaryocyte Reactions.**—The platelets in the circulating blood are of uniform structure and of common origin. The curve of regeneration after destruction or loss is independent of those of regeneration of red corpuscles and of leucocytes, but at the same time as or preceding the increase in the number of platelets in the blood stream the megalokaryocytes of the bone marrow are increased in number. Bunting corroborates the discovery of J. H. Wright that the blood platelets are formed by segmentation of portions of pseudopodia separating from the megalokaryocytes.

43. **Hemorrhagic Necrosis of Pancreas.**—Hemorrhagic pancreatitis, so-called, is in reality primarily a necrosis of the parenchyma of the pancreas and should be called hemorrhagic necrosis, the inflammatory changes present being secondary to the necrosis or subsequent to infection. The so-called pancreatic apoplexy is the result of acute necrosis of the pancreas. In some cases necrosis may lead to little or no hemorrhage. "Gangrenous pancreatitis" is a late stage of hemorrhagic necrosis, a most frequent cause of which, in man, is the entrance of irritating material into the ducts of the pancreas, such as bile diverted by a gallstone lodged at the duodenal orifice of the common duct. Duodenal contents entering the duct may have the same effect, and in a small proportion of cases necrosis may follow injury of the pancreas, being in this case probably in part referable to simultaneous thrombosis. Anatomic peculiarities or anomalies of the pancreatic ducts may predispose to hemorrhagic necrosis.

44. **Strains of Diplococci in Meningitis.**—No reliable points of difference were found between strains of *Diplococcus intracellularis* from typical cases of epidemic meningitis, and several strains of cocci obtained from cases of posterior basic meningitis. With diplococci obtained from posterior basic meningitis acutely fatal meningitis was produced in monkeys. Consequently antimeningitis serum should be used in case of posterior basic meningitis.

46. **Butyric Acid Test in Syphilis.**—The cerebrospinal fluid in syphilitic individuals, like the blood serum, contains more globulin, and especially euglobulin, than normally. By virtue of this increase the following butyric acid reaction is applicable to the diagnosis of syphilis: One or two parts of spinal fluid are mixed with five parts of 10 per cent. butyric acid solution and heated over a flame to a brief boiling. One part of normal solution of sodium hydroxid is then added quickly to the heated mixture and the whole is boiled once more for a few seconds. The presence of an increased content of protein in the spinal fluid is indicated by the appearance of a granular or flocculent precipitate which gradually settles under a clear supernatant liquid. The granular appearance of the precipitate is held to be a positive reaction for syphilis or parasyphilitic affections. It was found that in the second or third stages of syphilis without direct involvement of the nervous system the cerebrospinal fluid gave the butyric reaction feebly and under these conditions the fluid did not give the Wassermann test nor a positive cell count according to the method of Rabaut; in hereditary syphilis a positive butyric reaction was obtained in 90 per cent. and a positive Wassermann in about 80 per cent of the cases examined; in the cases of cerebral and spinal syphilis examined every one gave the butyric reaction and the cell count, the Wassermann reaction being obtained in from 50 per cent. to 75 per cent.; the cases of general paralysis gave positive butyric reaction in 90 per cent., positive cell counts in 91 per cent., and positive Wassermann in 73 per cent.; in cases of tabes, the cerebrospinal fluid gave a positive butyric reaction and cell count in 100 per cent., and a positive Wassermann in 53 per cent. From these and other facts it is concluded that the butyric

acid reaction may be a ready means of distinguishing normal from pathologic cerebrospinal fluid and that it will prove useful as a routine method especially in detecting syphilitic and metasyphilitic lesions of the central nervous system, being a valuable addition to the Wassermann test.

47. **Standardization of Antimeningitis Serum.**—It is proposed to employ the specific opsonin present in antimeningitis serum as a measure of the therapeutic power of the serum; for the present a definite and suitable strength in opsonins should be adopted as a standard for antimeningitis serum and a minimum dilution activity of a 1 to 5,000 dilution of the serum is proposed as such. The specific meningococco-opsonin appears to be stable under proper refrigeration of the serum, so that the test may prove applicable also for commercial antimeningitis serum.

67. **Typhoid.**—The results of this investigation support the view that the bacillemia of typhoid, as a rule, disappears at or about the time that convalescence begins. The theory of the authors in regard to the genesis of typhoid is briefly as follows: The entrance point is the lymphatic structures of the intestines, from which the bacilli enter the general lymphatic system and spleen, where they grow, and only relatively few are destroyed. During the incubation a limited number of bacilli may enter the blood but when the development of the bacilli reaches a certain point they enter the blood in large numbers and are then destroyed with liberation of endotoxins, the symptoms representing the reaction on the part of the host. As the disease advances in the typical case of typhoid progressing to recovery, the growth of bacilli in the organs is greatly arrested by the reactive processes of the host, fewer bacilli enter the blood, the symptoms diminish in severity. In fatal cases the growth of bacilli proceeds unchecked and the symptoms are not restrained, becoming perhaps even more intense. At or about the time of defervescence in the attack of typhoid, the bacilli practically disappear from the blood; the symptoms now come to an end and the convalescence proceeds nicely. In instances in which there is an intermittent fever not due to complication it is probable that the growth of bacilli in organs has not been checked and a limited number continue to enter the blood.

8 *An Easy Method of Removing the Nail of the Great Toe by Compression. P. Tytler

1. **Motor Area of the Brain.**—Horsley believes that the so-called motor area of the human cortex cerebri is really sensori-motor. The gyrus pre-centralis is in man the seat of representation of (1) slight tactility, (2) topognosis, (3) muscular sense, (4) arthric sense, (5) stereognosis, (6) pain, (7) movement. The gyrus post-centralis is in man part of the arm area in which the sensori-motor representation is of the same kind as that in the gyrus pre-centralis, but in it probably provision for sensorial co-ordination is greater, and that for efferent impulses less. The giant pyramids or Betz cells are not essential for the performance of purposive or voluntary movements. Purposive or voluntary movements can be performed after complete removal of the corresponding part of the gyrus pre-centralis.

4. **Treatment of Enlarged Prostate.**—Herring says that prostatectomy should not be undertaken unless the symptoms present are definitely ascertained to arise from that organ, and from nothing else. Prostatectomy should be deferred until after treatment by catheter has been tried. No harm can come of a delay of a month or more, and in septic cases much good will result, for the patient will improve and be in a better condition to bear the operation. Afterward, if the catheter fails or is found too irksome, recourse can be had to operation. When the patient is comparatively young, in good health, and has many years of life before him, operation is very rightly advocated as soon as it is proved that catheter treatment will not cure. The same may be said of those who, owing to their position in life, calling, or lack of funds, are unable to carry out the few simple details necessary in sterile catheterization. Prostatectomy undoubtedly is the best treatment when the prostate, by its mere size, has largely encroached on the bladder space, and there is no residuum. The urine is clear and free from all signs of sepsis, yet the patient has constant and urgent calls to pass water both by day and night. Finally, the operation may be necessary in certain cases in which the prostate is constantly bleeding and filling the bladder with clots which interfere with instrumentation and endanger the patient's life.

7. **Case of Landry's Palsy.**—The points of interest in Kapadia's case were: (1) Landry's palsy generally occurs between the ages of 20 and 30, but the patient under his observation was 60 years of age; (2) at first the case was difficult to diagnose, but later on, when the paralysis spread with such uniformity, as was noted, it was easy to diagnose.

8. **Easy Method of Removing the Nail.**—First of all, Tytler applies a compress of lead and opium for twenty-four hours. Then a tape is tied round the root of the toe till it produces intense congestion. Then he takes a large Pean's forceps with long parallel blades, and compresses the nail in the middle of the inner half with moderate firmness. A check as to the amount of compression can be introduced between the handles so as to prevent excessive pressure. Much less force is required than would be supposed. Then the toe is again wrapped in lead and opium lotion for three days. Then the inner part of the nail is found discolored and loose, so that it is easily removed with the scissors without any bleeding save a few drops from the root of the nail.

18 Case of Acute Lupus Erythematosus. J. E. R. McDonagh.

14. **Pulmonary Tuberculosis Treated by Mercuric Succinimid.**—Of the 13 patients who were treated, some, for various reasons, were not able to remain as long in the hospital as one could have wished in order to give the method a fair trial. The buttock was chosen as the most convenient place for injection, and every precaution was taken to sterilize both the needle and the part injected. For each injection 1/5 grain of mercuric succinimid was dissolved in 10 minims of distilled water; this was injected into the buttocks alternately every second day, Sunday being excluded. In the case of the females no injection was given during the menstrual period. In all cases careful attention was paid to the teeth and a mouth wash was used after each meal.

While none of the patients objected to the form of treatment, it can not be said that any of them liked it. With few exceptions there was always a brawny lump, varying from the size of the tip of one's little finger to the size of one's thumb or a little larger at the seat of injection for about 48 hours.

All the patients complained of a slight burning or pricking pain at the seat of injection for a time, varying from 6 to 12 hours. Three of the patients felt faint after the injection on three or four occasions, and one of them had a slight vomiting attack immediately after. The female patients complained less of pain than the males. This may be explained by the fact that Nature has provided them with more adipose tissue in that region and therefore sitting down would cause less discomfort.

The patients treated—six females and seven males—varied in age from 15 to 51 years; all, with one exception, were more or less advanced cases, three having cavities and all had tubercle bacilli in the sputum. In one case it was noticed that the sputum was swarming with bacilli on the first examination. About ten days later they were decreased by half, and in another week one had to look carefully for them, there were so few. In another case, though the physical signs decreased in severity, the bacilli increased in number. In most of the remaining cases the bacilli decreased in number and in one case none could be found after a couple of week's treatment.

A remarkable fact which applied to most of the cases was the rapidity with which the physical signs decreased. This continued for the first four or five weeks. Then, with two exceptions, most of the patients arrived at a stage where no further change could be made out, and some of them even returned to their former condition. In two cases the physical signs disappeared altogether.

1. Motor Area of the Brain.—Horsley believes that the so-called motor area of the human cortex cerebri is really sensori-motor. The gyrus pre-centralis is in man the seat of representation of (1) slight tactility, (2) topognosis, (3) muscular sense, (4) arthric sense, (5) stereognosis, (6) pain, (7) movement. The gyrus post-centralis is in man part of the arm area in which the sensori-motor representation is of the same kind as that in the gyrus pre-centralis, but in it probably provision for sensorial co-ordination is greater, and that for efferent impulses less. The giant pyramids or Betz cells are not essential for the performance of purposive or voluntary movements. Purposive or voluntary movements can be performed after complete removal of the corresponding part of the gyrus pre-centralis.

4. Treatment of Enlarged Prostate.—Herring says that prostatectomy should not be undertaken unless the symptoms present are definitely ascertained to arise from that organ, and from nothing else. Prostatectomy should be deferred until after treatment by catheter has been tried. No harm can come of a delay of a month or more, and in septic cases much good will result, for the patient will improve and be in a better condition to bear the operation. Afterward, if the catheter fails or is found too irksome, recourse can be had to operation. When the patient is comparatively young, in good health, and has many years of life before him, operation is very rightly advocated as soon as it is proved that catheter treatment will not cure. The same may be said of those who, owing to their position in life, calling, or lack of funds, are unable to carry out the few simple details necessary in sterile catheterization. Prostatectomy undoubtedly is the best treatment when the prostate, by its mere size, has largely encroached on the bladder space, and there is no residuum. The urine is clear and free from all signs of sepsis, yet the patient has constant and urgent calls to pass water both by day and night. Finally, the operation may be necessary in certain cases in which the prostate is constantly bleeding and filling the bladder with clots which interfere with instrumentation and endanger the patient's life.

7. Case of Landry's Palsy.—The points of interest in Kapadia's case were: (1) Landry's palsy generally occurs between the ages of 20 and 30, but the patient under his observation was 60 years of age; (2) at first the case was difficult to diagnose, but later on, when the paralysis spread with such uniformity, as was noted, it was easy to diagnose.

8. Easy Method of Removing the Nail.—First of all, Tytler applies a compress of lead and opium for twenty-four hours. Then a tape is tied round the root of the toe till it produces intense congestion. Then he takes a large Pean's forceps with long parallel blades, and compresses the nail in the middle of the inner half with moderate firmness. A check as to the amount of compression can be introduced between the handles so as to prevent excessive pressure. Much less force is required than would be supposed. Then the toe is again wrapped in lead and opium lotion for three days. Then the inner part of the nail is found discolored and loose, so that it is easily removed with the scissors without any bleeding save a few drops from the root of the nail.

14. Pulmonary Tuberculosis Treated by Mercuric Succinimid.—Of the 13 patients who were treated, some, for various reasons, were not able to remain as long in the hospital as one could have wished in order to give the method a fair trial. The buttock was chosen as the most convenient place for injection, and every precaution was taken to sterilize both the needle and the part injected. For each injection 1/5 grain of mercuric succinimid was dissolved in 10 minims of distilled water; this was injected into the buttocks alternately every second day, Sunday being excluded. In the case of the females no injection was given during the menstrual period. In all cases careful attention was paid to the teeth and a mouth wash was used after each meal.

While none of the patients objected to the form of treatment, it can not be said that any of them liked it. With few exceptions there was always a brawny lump, varying from the size of the tip of one's little finger to the size of one's thumb or a little larger at the seat of injection for about 48 hours.

All the patients complained of a slight burning or pricking pain at the seat of injection for a time, varying from 6 to 12 hours. Three of the patients felt faint after the injection on three or four occasions, and one of them had a slight vomiting attack immediately after. The female patients complained less of pain than the males. This may be explained by the fact that Nature has provided them with more adipose tissue in that region and therefore sitting down would cause less discomfort.

The patients treated—six females and seven males—varied in age from 15 to 51 years; all, with one exception, were more or less advanced cases, three having cavities and all had tubercle bacilli in the sputum. In one case it was noticed that the sputum was swarming with bacilli on the first examination. About ten days later they were decreased by half, and in another week one had to look carefully for them, there were so few. In another case, though the physical signs decreased in severity, the bacilli increased in number. In most of the remaining cases the bacilli decreased in number and in one case none could be found after a couple of week's treatment.

A remarkable fact which applied to most of the cases was the rapidity with which the physical signs decreased. This continued for the first four or five weeks. Then, with two exceptions, most of the patients arrived at a stage where no further change could be made out, and some of them even returned to their former condition. In two cases the physical signs disappeared altogether.

health is yet able to protect against new infection, unless the opportunities for new infection are so numerous and the infection so intense that it overcomes the influence of the protecting immunization. A slight early tuberculous process thus protects the individual against mild new infection. The tuberculous individual reacts to severe new infection by the development of slow phthisis, while the normal individual under the same conditions reacts with acute miliary tuberculosis. The aim in prophylaxis should be to avoid severe new infection. This can be done by restricting the opportunities for family and house infection, or by protective vaccination, or by preventing autoinfection from the already tuberculous organism, or by these combined. Some stereoscopic views of the findings in the lungs of the guinea-pigs are given to show the difference between the reaction to new infection in the normal and the infected lungs.

43. **Prophylaxis of the Mechanical Predisposition of the Apices to Tuberculosis.**—Koch has practiced in the tropics and has been impressed with the remarkable development of the chest in native races, its broad outlines and expansion, all in such contrast to the narrow, almost concave chest of civilized peoples. He is convinced that this difference is the result of habits of clothing and schooling, and that until these are changed no effectual prophylaxis against the "white plague" is possible. He declares that the imagination can not conceive of any article better adapted to check the development of the chest of the child and the lungs within than the suspenders and skirt supporters worn by children nowadays. The shoulders and upper part of the lungs are compressed by them, and this pressure keeps up all day long, the weight of things in the pockets adding to the drag on the shoulders. The supporters over the shoulders are held down as the child sits on the trousers or skirts. The bones, cartilages, muscles and lungs are kept constantly compressed and are thus unable to develop and the compressed portion of the lungs and apex thus remains a place of lesser resistance all through life. The effect of compression on liver and kidneys from the wearing of corsets, and the influence of immobilization on the healing of fractures and pleurisy, demonstrate the great influence of external agencies on the development of parts and organs beneath. Injury from the clothing is supplemented by injury from long sitting in school, the bad air and the lack of opportunities for oxidation processes in the body cells. The heart also suffers from the lack of development of the chest and a vicious circle is set up. He concludes his article with an appeal for space in the growing lungs, freedom for the apices and shoulders, and more out of door air and exercise.

44. **Diazoreaction in Tuberculosis.**—Gwerder emphasizes the importance of the diazoreaction in pulmonary tuberculosis as it gives valuable information in many cases in regard to the intensity and probable course of the disease. The test should be repeated several times as single findings are not conclusive.

45. Abstracted in The Journal, July 4, 1908, p. 72.

47. **Hemoptysis as Early Symptom of Pulmonary Tuberculosis.**—Müller states that hemoptysis was an early symptom in 170 of the 875 tuberculous patients at the Davos German Sanatorium during the last four years. Early hemoptysis was twice as frequent in the male as in the female patients, but none of them displayed a greater tendency to hemorrhage later than other groups of patients. The alarm from the early hemoptysis generally has a salutary effect, as vigorous treatment is instituted earlier. After nine months or a year in the sanatorium full earning capacity was restored in 71 patients and partial in 60 others; one patient succumbed to miliary tuberculosis.

50. **Bacterial Content of Normal Organs.**—Conradi has perfected a technic which protects organs against contamination from without while favorably influencing bacterial proliferation, and his examination of 162 apparently normal organs taken from 150 recently slaughtered healthy animals has given surprising results. In 72 of the 162 organs bacteria were found; they were of a number of species, the colon bacillus most common. The bacterial findings were positive in 42 of the 63 livers examined; in 18 of the 59 pieces of muscles; in 6 of the 19 kidneys; in 4 of the 5 lungs, and in 1 of the 11 spleens. Anaërobic species were found in 30 of the 72 positive cases. This latent vegetation of bacteria in the organs throws light on the origin of cryptogenic and autoinfections, and also shows the necessity for revision of the present methods of meat inspection. With his technic a piece of the organ about 50 gm. in weight is cut out with a sterile knife and forceps and plunged at once, for a minute at least, into oil heated to 200 C. and then transferred for four hours to a solution of 2 per cent. mercuric chlorid. It is then placed in a large conical glass with hermetically closing cover and kept at 37 C. for twenty hours. The chunk is then cut in half and from the center of one half scraps are taken for culture of anaërobes in a fluid gelatin medium, while a scrap from the other half is transferred to a plate culture and the Gram technic is also applied to a specimen. The hot oil sears the outside of the chunk, while the bacteria are enriched by the long incubation.

52. **Intraperitoneal Hemorrhage with Stab or Firearm Wounds of the Intestines.**—Gutzeit reports a case which confirms his assumption that the hemorrhage and perforation are liable to counteract each other. If the blood pours out quicker than the bowel content it dilutes and checks the latter and aids in the encapsulation, both mechanically and by its protecting substances. On the other hand, the hemorrhage is arrested by the tension of the abdominal wall and the distension and paralysis of the intestines.

56. **Utilization of the Natural Defenses in Treatment of Perforation Peritonitis.**—Janssen describes the technic used at Witzel's clinic for drainage of the abdomen in case of appendicitis and diffuse peritonitis. The aim is to keep the parts from sticking together, to insure drainage of the depths and ample outflow. No attempt is made to rinse out the abdominal cavity but every effort is devoted to autoirrigation, that is, to utilize the enormous secreting capacity of the peritoneum. By supplying large amounts of fluid the peritoneum is induced to secrete copiously and this is drained rapidly away, thus flushing the peritoneum from within in the most effectual manner. The stomach and bowel can not be relied on, and consequently the fluid is infused subcutaneously. Physiologic salt solution is thus given four or five times a day, including the night, so that three or four liters of fluid are thus incorporated in twenty-four hours, and this is kept up, grad-

33 Trauma in Relation to Malignant Tumors. J. Bland-Sutton.
34 Some Points in the Surgical Treatment of Fracture of the Base of the Skull. L. B. Rawling.

30. **Ectopic Pregnancy.**—Herman claims that the diagnosis of tubal pregnancy before hemorrhage has occurred is impossible. The diagnosis of a tubal mole from some other conditions is difficult, but nearly all the conditions which may reasonably be mistaken for a tubal mole equally require prompt operation. Slight hemorrhage from perforation of a pregnant tube is often accompanied by death of the fetus and rapid absorption of the effused blood. When great intraperitoneal hemorrhage has taken place from perforation of a pregnant tube operation is urgent and simple. The danger from delay in operating is greater than that coming from the inexperience of the operator, if only he be one who understands antisepsis. After perforation of a pregnant tube the amnion may protrude into the peritoneal cavity, and the child grow free among the bowels, covered only by its amnion. In that case the placenta, as it grows, may become implanted on almost any abdominal viscus, and cover a large area. In such cases it is probable that after the primary preparation the mother runs hardly any risk until after the death of the child. In such cases, operation while the child is viable is an extremely dangerous one, and is more dangerous the more advanced the pregnancy. The danger is from hemorrhage resulting from separation of the placenta. The experience of more recent operators shows that it is nevertheless safer to remove the placenta than to leave it to come away. The methods of preventing such hemorrhage which have proved successful are: (a) the removal when possible of the viscera to which the placenta is attached; and (b) extensive prophylactic ligature of the arteries supplying the placental site. If the operation is postponed until after the death of the child, some time afterward (unfortunately we know not exactly how long) the circulation through the placenta ceases, and it becomes thrombosed. If an operation is now done the placenta can be peeled off without hemorrhage, and the operation is simple and safe. When the pregnancy is underneath the peritoneum there is danger of rupture at any period of the pregnancy. Therefore in this case the sooner operation is done the better.

38 *Diagnosis and Treatment of Insufficiency of the Suprarenals. (Insuffisance surrénale.) E. Sergent.
39 *The Surgical Profession in America. S. Pozzi.

38. **Suprarenal Insufficiency.**—Sergent analyzes the symptoms of suprarenal insufficiency affecting the circulation, the digestion, the nervous system and the general metabolism. The syndrome of suprarenal insufficiency may be slow or acute. *In the chronic form,* of which Addison's disease is the extreme type, if there is no bronzing, it can be rendered manifest by applying a mustard plaster which draws the pigment to the surface. The tuberculous process in the suprarenals in this disease is almost always primary, and these glands are rarely affected even with advanced tuberculosis in other organs. Without the bronzing, the syndrome suggests pernicious anemia, leukemia or latent cancer, especially the weakness, the low blood pressure, the loss of appetite, the constipation, vomiting, anemia and progressive emaciation. The acute form may simulate a fulminating poisoning, peritonitis, meningitis, apoplectiform coma, etc., and it may be suspected when the febrile and other phenomena of an infectious disease are suddenly supplanted by signs of depression, small, unstable pulse, subnormal temperature and arterial tension. He is convinced that the "white line"-is pathognomonic of suprarenal insufficiency and it may prove very instructive in cases of sudden death from this cause in which circumstances indicate possible poisoning or violence. Besides trauma, an operation or even a pregnancy may *bring on this acute insufficiency* on the part of the suprarenals. Treatment should aim to prevent the development of the acute phase or exacerbations in persons already affected with the chronic form. They should avoid exertions and contact with persons suffering from infectious diseases and should refrain from toxic drugs, especially from arsenic, which is a violent poison in case of suprarenal insufficiency, and they should not permit any surgical operations unless for vital necessity. On the other hand, they will derive benefit from phosphates and especially from lecithin. Antisyphilitic treatment should be instituted if there is a possibility of a syphilitic origin, but the mercury and iodid must be managed with great care as they are liable to prove poisonous for the suprarenal capsule. Suprarenal organotherapy is useful both for differentiation and cure, and he has witnessed the entire subsidence of the Addison syndrome, including the disappearance of the "white line" under the influence of suprarenal medication. Fresh glands from young calves may be used, the patient ingesting from 1.5 to 2 gm. a day up to 5 gm., or the dry extract can be taken. This is kept up for ten or twelve days, then suspended for two or three, and then recommenced. As a rule, he prefers the extract of the whole gland, but he sometimes uses adrenalin. He has found this particularly useful in infectious diseases when he suspected suprarenal involvement. Signs of cardiovascular weakness subside under the influence of the adrenalin, and the white line vanishes and reappears parallel with the fluctuations of the pulse, which he regards as substantial proof of its pathognomonic character. The usual dose is 0.001 gm. a day, but up to 0.006 may be given fractioned in 6 doses, and this, he says, may be kept up for two months. The white line is the opposite of the "red line" of meningitis. The finger is drawn lightly along the skin of the abdomen; in a few seconds the path of the finger shows up as a white stripe, growing more and more distinct and remaining stationary for three or four minutes and then disappearing.

42. **Immunity of the Tuberculous to Tuberculosis.**—Römer reports a series of experiments undertaken to determine the power of resistance of tuberculous animals to renewed infection. The results show that spontaneous tuberculosis of a chronic character protects guinea-pigs against renewed infection. The protection is more decided the more chronic the first infection and the longer the interval since the first symptoms. Comparing these results with clinical experience shows that a *first infection which does not affect materially the general*

health is yet able to protect against new infection, unless the opportunities for new infection are so numerous and the infection so intense that it overcomes the influence of the protecting immunization. A slight early tuberculous process thus protects the individual against mild new infection. The tuberculous individual reacts to severe new infection by the development of slow phthisis, while the normal individual under the same conditions reacts with acute miliary tuberculosis. The aim in prophylaxis should be to avoid severe new infection. This can be done by restricting the opportunities for family and house infection, or by protective vaccination, or by preventing autoinfection from the already tuberculous organism, or by these combined. Some stereoscopic views of the findings in the lungs of the guinea-pigs are given to show the difference between the reaction to new infection in the normal and the infected lungs.

43. **Prophylaxis of the Mechanical Predisposition of the Apices to Tuberculosis.**—Koch has practiced in the tropics and has been impressed with the remarkable development of the chest in native races, its broad outlines and expansion, all in such contrast to the narrow, almost concave chest of civilized peoples. He is convinced that this difference is the result of habits of clothing and schooling, and that until these are changed no effectual prophylaxis against the "white plague" is possible. He declares that the imagination can not conceive of any article better adapted to check the development of the chest of the child and the lungs within than the suspenders and skirt supporters worn by children nowadays. 52. **Intraperitoneal Hemorrhage with Stab or Firearm Wounds of the Intestines.**—Gutzeit reports a case which confirms his assumption that the hemorrhage and perforation are liable to counteract each other. If the blood pours out quicker than the bowel content it dilutes and checks the latter and aids in the encapsulation, both mechanically and by its protecting substances. On the other hand, the hemorrhage is arrested by the tension of the abdominal wall and the distension and paralysis of the intestines.

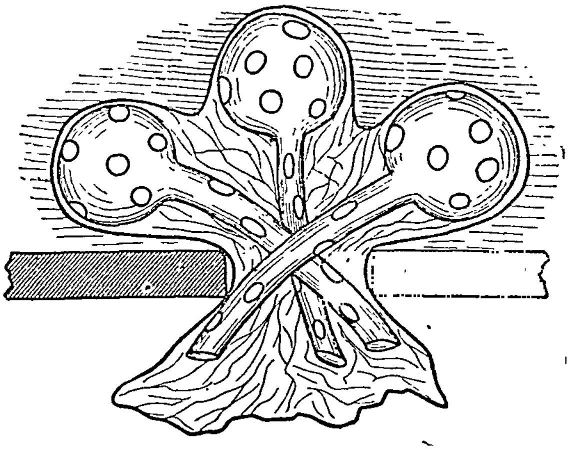
56. **Utilization of the Natural Defenses in Treatment of Perforation Peritonitis.**—Janssen describes the technic used at Witzel's clinic for drainage of the abdomen in case of appendicitis and diffuse peritonitis. The aim is to keep the parts from sticking together, to insure drainage of the depths and ample outflow. No attempt is made to rinse out the abdominal cavity but every effort is devoted to autoirrigation, that is, to utilize the enormous secreting capacity of the peritoneum. By supplying large amounts of fluid the peritoneum is induced to secrete copiously and this is drained rapidly away, thus flushing the peritoneum from within in the most effectual manner. The stomach and bowel can not be relied on, and consequently the fluid is infused subcutaneously. Physiologic salt solution is thus given four or five times a day, including the night, so that three or four liters of fluid are thus incorporated in twenty-four hours, and this is kept up, grad-



ually reducing the amounts, for six or seven days. The drainage is by hollow glass balls with a long stem studded thick with perforations (see illustration); the balls are from 1 to 3 cm. in diameter. A piece of gauze is fitted into the cavity, as for a Mikulicz tampon, and then the ball drains are introduced, the stems emerging from the operative wound. The patient lies permanently on his right side, thus insuring ample outflow of the fluid. Of equal importance is the supervision of the action of the heart, and digitalis is given systematically before and after the operation, and other stimulants are used at the slightest signs of flagging on the part of the heart. Great stress is also placed on the application of warmth, not only to prevent collapse but to induce active hyperemia in the organs inside the peritoneum and thus promote the activity of the bowels. The heat is applied in the form of hot compresses, poultices or a thermophore. The intestines are also stimulated by introduction of the intestinal tube; drugs are seldom necessary. The treatment of the peritonitis thus begins as soon as the patient returns to his bed after the operation and includes these four important factors: stimulation of the heart action and bowel *functioning, application of heat and copious auto-irrigation* of the abdominal cavity.

Wiener klinische Wochenschrift, Vienna

July 1, XXII, No. 26, pp. 911-948

57 Condensed Human Milk in Infant Feeding. (Ernährungsversuche bei Neugeborenen mit konservierter Frauenmilch.) E. Mayerhofer and E. Pribram.
58 *Non-Diabetic Glycosuria. K. Glaessner.
59 *Improved Instrumental Technic for Gastroenterostomy. (Instrument zur Anlegung von Magen- und Darmanastomosen.) R. Frank.
60 *Improved Technic for Cultivation of Spirochetes. (Untersuchung der Spirochaete pallida mit dem Tuschverfahren.) V Hecht and M. Wilenko.

58. **Non-Diabetic Glycosuria.**—Glaessner discusses glycosuria from hyperglycemia and alimentary glycosuria, the toxic from chemical and thermic injury and bacteria, and the glycosuria of levulosuria, lactosuria, galactosuria, pentosuria and elimination of glucuronic acid. He has noticed that transitory glycosuria from asphyxia, carbon monoxid poisoning and exposure to cold is always accompanied by lactic acid in the urine. He has never detected lactic acid in the urine in diabetes and thinks that this may sometimes aid in differentiation.

59. **Instrument for Anastomosis.**—The two branches of the instrument are inserted separately, one in a buttonhole in the stomach wall, the other in a buttonhole in the loop of the intestine, when gastroenterostomy is contemplated. The branches are thus introduced in opposite directions. The two branches are then brought into juxtaposition and the handles screwed tight together. The serosa of the bowel and stomach is then sutured together, first on one side of the instrument and then on the other. A slender knife is then introduced between the blades and the lumen opened with it, after which the instrument is removed and the buttonholes sutured. Frank claims a number of advantages for this instrument.

60. **India Ink Method for Studying Spirochetes.**—Burri has materially simplified bacteriologic research by his India ink method. A droplet of the fluid to be examined is mixed with a droplet of India ink on an object glass and allowed to dry. Examined then through the microscope the bacteria stand out as with the dark field illumination. Hecht states that the method is particularly useful for examining spirochetes, so that any practitioner in less than a minute can reveal the *Spirochæta pallida* in case of positive findings.

63 Parametritis and Posterior Paravaginitis with Heterotopic Proliferation of Epithelium. R. Meyer.

61. **Lactic Acid in the Blood and Urine in Epilepsy and Eclampsia.**—Zweifel has been continuing his study of this subject since he reported the constant finding of lactic acid in the urine in 17 cases of eclampsia. He has found small amounts in the urine in 5 cases of "pregnancy kidney" and large amounts in 3 cases of "pregnancy nephritis." He thinks this finding is important as this latter condition is the preliminary to eclampsia. Examination of the urine of three epileptics showed no trace of lactic acid in one and very little in the other, but in a third case 1.489 gm. of lactic acid were found in 845 c.c. of urine at one time and 3.369 gm. in 505 c.c. at another time. The seizures in this last case were very severe and in the intervals the patient was apathetic. Meat was dropped then from the diet of this epileptic, after which lactic acid could no longer be detected in the urine; there has been no recurrence of seizures and the patient is less apathetic. These findings confirm the assumption that tonic general convulsions are merely a symptom and that epileptic seizures may occur from very different causes.

67 Fracture of Sphenoid Bone from Direct Trauma. (Frattura dello sfenoide da causa diretta.) T. Costa and C. Migliucci.

64. **The Work of the Heart.**—Silvestri relates some experiences and discusses physiologic findings which demonstrate that the mechanical work of the heart is much less than generally assumed, owing to certain mechanical factors which he enumerates. Also that the heart is capable of exertion six or seven times as great as its normal work, and is able to get along without inducing symptoms sometimes when its working capacity is reduced to a fraction of normal.

66. **Stain for Spermatozoa.**—Baecchi states that his technic is extremely simple and rapid, while it shows up the spermatozoa in a few seconds and the stained specimens are durable. A thread of the soiled tissue is placed in a concentrated aqueous solution of acid fuchsin for 25 or 30 seconds; then transferred to a 1 per cent. alcoholic solution of hydrochloric acid in 70 per cent. alcohol for from 10 to 30 seconds, until decolored to a pale pink; it is then placed in absolute alcohol for 15 to 20 seconds. The thread is then transferred to an object glass in a drop of xylol and the fibers separated when it is ready for the microscope. The heads of the spermatozoa show bright red while the thread fibers are decolored or only slightly pinkish. The most perfect specimens are obtained when the thread is first soaked in distilled water for a few hours. A counter stain with methylene blue shows up the spermatozoa even more perfectly.

Address

THE PART SANITATION IS PLAYING IN THE CONSTRUCTION OF THE PANAMA CANAL *

WILLIAM C. GORGAS, M.D.
Colonel, U. S. Army; Chief Sanitary Officer, Isthmian Canal Zone; President, American Medical Association
ANCON, PANAMA

The best way of showing what part sanitation is playing in the present canal work is to point out what the conditions would be if the present methods of sanitation were not in vogue, and then to present conditions as they actually are. The difference between the two pictures will fairly represent what is due to sanitation.

For some years the Isthmus of Panama has had about as bad a reputation for health as any locality in the world. Probably it would not be extreme to say that there is no other place that had as bad a reputation. The English official guide for pilots for the year 1903 made these remarks about the canal district:

> The Panama Canal District is one of the hottest, wettest and most feverish regions in existence. Intermittent and malignant fevers are prevalent, and there is an epidemic of yellow fever at times. The death rate under normal conditions is large.—*West India Pilot*, vol. i, 6th ed., 1903.

The history of the Isthmus amply justifies this reputation. Panama is nine degrees north of the equator. It has a heavy rainfall—about 71.70 inches (a ten years' average) at Ancon on the Pacific side, and 128.37 inches (average for thirty years) at Colon on the Atlantic. The temperature is warm all the year round, sufficiently so for mosquitoes to breed freely in all seasons. From the year 1520 it has been the favorite point in the western hemisphere for transit between the Atlantic and Pacific coasts. Towns of considerable size have been located on the Isthmus since that time. These towns have always had to rely for their water supply on rain water collected in cisterns and barrels. The yellow fever mosquito, the stegomyia, requires a warm climate for its existence; it can not survive frost. For laying its eggs and rearing its larvæ it needs rain water in a protected locality. For the development, then, of this particular species of mosquito the Isthmus of Panama possesses in an eminent degree all the requirements; namely, a warm climate, large rainfall, and towns almost entirely dependent on collected rain water for their supply.

Many other tropical American cities are just as favorably situated for the development of the yellow fever mosquito as is the city of Panama, so we must look for some other element, not present in them, as a cause for the pre-eminent reputation which the Isthmus of Panama has obtained as a yellow fever center. Wherever yellow fever prevails endemically the native population becomes immune to the disease. This is generally explained by saying that the native, as a child, has a mild attack of the disease which protects him in after-life. It is a fact that an attack of yellow fever gives the individual entire protection—about as much so as does an attack of smallpox. Therefore, when yellow fever has prevailed for a longer or shorter period in a locality, all the people capable of having the disease contract it and become immune. There being no more material for the disease to feed on, it dies out and disappears. If, however, a constant stream of foreigners is poured into this locality, they keep up the disease, and yellow fever will continue as long as the supply of non-immunes continues.

I would state, then, that for the most favorable development of yellow fever three things are essential: (1) a hot climate all the year around; (2) an abundant supply of fresh water stored near human habitations, and (3) a steady influx of foreigners who have not had the disease.

Let us take a few localities in which yellow fever has prevailed as illustrative of this view. Philadelphia has suffered many times, and severely, from yellow fever. At the period at which that city suffered from this disease only two of the elements favorable to its spread were present, namely, a large number of non-immune, and an abundant supply of well- and rain-water. Philadelphia is north of the natural habitat of the stegomyia mosquito, and it is found there only when introduced during the warm summer weather by shipping from the South. The cold winters destroy all yellow fever mosquitoes that survive the summer. The change from sailing to steam vessels has greatly decreased the number of times that stegomyia are introduced every summer into Philadelphia, and the introduction of a piped water supply has decreased their ability to find breeding-places when introduced. Philadelphia, therefore, has not suffered from yellow fever for fifty years, and probably would not again, even if we did not know that the mosquito transmitted the disease.

New Orleans is more favorably situated for yellow fever. It has two of the essentials for the *maximum* development—a steady influx of non-immune foreigners and an abundant supply of rain water stored close to human habitations. But the element of climate is against yellow fever becoming endemic. While New Orleans is within the stegomyia belt, the winters are sufficiently cold to destroy most of these mosquitoes, and for this reason yellow fever has never become endemic there for any number of years.

In Havana, Cuba, we have all three of the elements favorable for yellow fever. It has a climate sufficiently warm for the stegomyia mosquito to breed all the year around. While the winters are cool, the temperature is never low enough to frost, and, though the breeding of the yellow fever mosquito greatly decreases during January, February and March, in favorable localities they develop freely during these months. Rain water stored in and about the houses in barrels and cisterns was universal, and there was a large influx of Spanish immigrants and other foreigners. Consequently Havana was one of the principal centers of yellow fever. From 1760 to 1901 there was probably not a month in which yellow fever did not occur.

---

* Address delivered at Jefferson Medical College, June 7, 1909.

In Panama the three essential elements for the development of yellow fever exist in the highest degree of perfection. The climate is warm all the year around. There is no difference in thermometric conditions between summer and winter. Wells and cisterns were generally depended on for the water supply, but the principal dependence was in rain water stored in barrels and cisterns. As the dry season lasts four months, and scarcely any rain falls during this time, rain water had to be stored in large quantities. For four hundred years the supply of non-immunes has been constant. This, I think, is the reason that Panama has acquired its preeminent reputation as an unhealthful locality. Many other localities in tropical America are just as favorably situated as is the Isthmus of Panama in respect to the first two elements (temperature and water supply) for the development of yellow fever, but no other locality approaches it in the third element. For four hundred years there has never been any interruption to the steady stream of foreigners who have crossed the Isthmus. These were food for yellow fever, and kept the disease alive in Panama. From our knowledge of yellow fever, and what we have seen in Panama, I believe that yellow fever has always existed there from the first Spanish settlement. Years can be found when no yellow fever was reported, but whenever a new garrison arrived, or a considerable number of non-immunes came, enough people died of the disease to attract attention, and yellow fever was reported. For the first three hundred years of the occupation of the Isthmus the principal travel consisted of the officials and employés (military and religious) of the great Spanish vice-royalty on the west coast of South America. Many of these died in Panama, and, as now and then an official of high rank would die, Panama obtained an exceedingly bad reputation all over the Spanish world.

About 1849, and for many years after, the rush of gold seekers to California took place. These suffered severely, and still further added to the unfortunate reputation of the Isthmus among English-speaking nations.

From 1850 to 1855 the Panama Railroad was under construction. The considerable force engaged in this work suffered so severely from the disease that work had to be stopped several times. By the authorities, the unfavorable health conditions were looked on as the principal obstacles to be overcome. From 1883 to 1889 the French had a large working force working on the canal. These also suffered very severely from disease, and this was considered one of the chief elements in their failure. The French experience on the Isthmus settled the reputation of Panama as to health conditions.

When the United States took possession in 1904 the Isthmus was generally looked on as probably the most unhealthy locality known. This was due, as I have pointed out, not so much to local conditions, as to the fact that no other tropical city has had for the same length of time such a steady supply of non-immunes. Many other tropical cities are just as well adapted to the development of yellow fever as is Panama, as far as the first and second conditions (temperature and water supply) are concerned, but none have had for anything like so long a time the third condition, namely, a steady inflow of foreigners.

There are no means of giving figures as to the death rates on the Isthmus. Until our arrival no general records were kept. We can obtain some basis for comparison by taking the records of the French Company. They had an excellent hospital, Ancon, where employés of contractors were treated at a charge of a dollar per day. But the contractor did not send many of his negro employés there. It was cheaper for him to discharge them. The hospital soon became infected with yellow fever, and non-immunes admitted generally contracted this disease. So the hospital was not very popular among the non-immunes. Many of the French employés when sick preferred to remain at their homes in Panama and Colon.

The records of Ancon Hospital were very accurately kept and are very good. During the nine years of the prosecution of the work under the French, 1,041 patients died of yellow fever in that hospital. As the Jamaica negro is not susceptible to yellow fever, the figures apply to whites alone, who are mostly Frenchmen. These are the figures for Ancon Hospital alone. They do not include those who died all along the line of the canal and in the cities of Panama and Colon. Probably at least as many died out of hospital as in it, and, while this is, of course, an estimate, I think it a very conservative one. This would give 2,082 deaths from yellow fever among the white French employés. The French averaged 1,606 white employés on their rolls. This means that the French lost five-fourths of their force in nine years or eleven-sixteenths in five years.

We have now been at work on the Isthmus five years. Our average white force has been 6,449. If we had lost at the same rate as I estimate the French did, we should already have buried 4,433 white men from yellow fever alone. We have an average of 4,852 Americans, including employés, their wives and children. At this rate we should by this time have lost from yellow fever 3,333 Americans.

Taking the stories of the survivors of families and small parties who came to the Isthmus during the French construction and also our general knowledge of yellow fever, I think the losses were larger than the above figures show. The family of one of the chief engineers consisted of five; four died of yellow fever. The family of the superintendent of the railroad consisted of five; three of these died of yellow fever. A party of seventeen engineers came on one steamer; sixteen of these died of yellow fever. Twenty-four sisters of charity came to Ancon Hospital at one time; twenty of these died of yellow fever. So from our knowledge of the conditions as they existed on the Isthmus and our general knowledge of yellow fever, I think it quite reasonable to say that one-third of the Frenchmen who came to the Isthmus during the French construction died of this disease.

Now let us see if we can estimate what this number was, taking our data from still another source. To keep an average of 4,852 Americans on the Isthmus connected with the work, we have had to bring to the Isthmus 24,260. It was estimated by the Department of Labor, Quarters and Subsistence, when that department was in existence, that the white gold roll is changed approximately about once a year. Estimating for the French in the same way, it would have been necessary to bring to the Isthmus in five years 8,330 Frenchmen, in order to keep their force up to 1,606. One-third of this number would give 2,770 as the deaths due to yellow fever. Applying this same ratio to the 24,260 Americans brought to the Isthmus in the past five years, we should have lost by this time 8,087 from this disease.

Now let us take the total force. The French average during their nine years was 10,121. They had in Ancon Hospital 5,651 deaths. The French were building the canal at Panama just as the subway in New York City was built, so far as police control is concerned. If a laborer got sick and went to his home and died, they had no means of finding out what became of him, any more than has the contractor on the subway in New York City. The man was simply dropped from the rolls. If he died in the hospital, he was recorded as a death, but not otherwise. The whole French canal was under construction by contract, and a contractor was charged a dollar per day for each patient he kept in hospital. The general opinion is that a very small proportion of the sick laborers were sent in. My experience with contractors teaches me that very few patients would come to the hospital if the contractor were charged a dollar a day for their care. The British minister at Panama tells me that he thinks that it would be a large estimate to say that one-fourth of the laborers who died, died in hospital. The present minister was there all during the construction days, and came in contact a great deal with the Jamaica negroes, who are British subjects and make up the bulk of the laboring force under the French. After giving the matter careful consideration, I think it fair to say that two men died out of hospital for every one who died in hospital. Estimating on this basis, and knowing that 5.651 died in hospital, we would have the total loss of 16,593. That is, the loss was eight-fifths of the average force.

The average American force for the past five years has been 26.532. Eight-fifths of this would be 42.449, which would be the number of deaths for nine years. For five years this would give us 23,580. I, therefore, make this claim for the sanitary work done on the Isthmus, that had not this work been done, we would have had the same losses as occurred under the French régimé.

At the end of the fifth year of work, this loss from yellow fever alone would have been, according to the French hospital figures, 3,463 Americans; according to my estimate, 8,087. The actual loss has been NINETEEN. At the end of five years from all causes and in the whole force, this loss would, according to my estimate, have been 23.850. Our actual loss has been 3,317.

The Card Index for Health of School Children.—The School Hygiene Association in France is making a valiant effort to have a system of card records adopted for each child. The card is to record the findings at each of the periodical visits of the medical school inspector, the physician merely noting that this or that organ or system of organs is defective, the weight or growth below standard, etc. The medical inspector does not state the nature or cause of the functional or organic disturbances he detects but merely notifies the parents that the child requires medical attention along certain lines, and that their family physician will diagnose the trouble and institute treatment. The card is the property of the scholar and is delivered to him as he leaves school, but is kept by the medical inspector in the meanwhile.

THE TREATMENT OF INFANTILE DIARRHEAS DUE TO INTESTINAL FERMENTATION WITH LACTIC ACID BACILLI*

CHARLES HUNTER DUNN, M.D.
Clinical Instructor in Pediatrics, Harvard Medical School; Assistant Physician at the Children's Hospital; Assistant Physician and Pathologist at the Infants' Hospital
BOSTON

Modern classifications of the diarrheal diseases of infancy reject the term "summer diarrhea" as having no scientific foundation, since investigation has shown that the diarrheas occurring in the summer months present no etiologic, anatomic or clinical peculiarities distinguishing them from those occurring at other times of year. The only foundation for this term is the great frequency of these diseases during the hot months, the explanation of this frequency being the effect of hot weather both in lowering the infantile digestive powers and in increasing the opportunities for the contamination of food supplies. The term "summer diarrhea" is used here, therefore, only as a convenient name under which to group diarrheal diseases on which a series of investigations were made during the hot months.

The classification of the diarrheal diseases has been much discussed without final or definite agreement as to either its basis or its terminology. I believe that an etiologic basis is the only one in line with the most recent scientific advance. Under such a classification the diarrheal diseases fall naturally into four divisions, having as their fundamental etiologic factors: first, nervous influences; second, indigestion; third, bacterial fermentation, and, fourth, bacterial infection, respectively. The details of this classification have been sufficiently described elsewhere.

THE RÔLE OF BACTERIA

Some distinguished pediatrists have been unwilling to accept the distinction found in the last two divisions of this classification, contending that bacteria form but one etiologic factor, and that all diarrheal diseases caused by the action of bacteria should be designated as infectious. Nevertheless, into such a classification a certain amount of confusion in terminology at once enters, such terms as dysentery, ileocolitis, infectious diarrhea, fermental diarrhea, acute gastrointestinal intoxication, all referring to diarrheal diseases caused by bacteria, yet presenting various differences in their etiology, anatomic and clinical descriptions. The distinction between the conditions caused by true bacterial infection with parasites, which live in and on the tissues of the body, and those caused by bacterial fermentation with saprophytes, which live in and on the intestinal contents, I believe to be essential. Such a fundamental distinction removes much of the confusion. Under it the term infectious diarrhea may be selected to include all cases in which there is true infection with parasites, while the term fermental diarrhea, or acute intestinal indigestion of the fermentation type, may be selected to include all cases in which the fundamental etiologic factor is saprophytic fermentation. The term ileocolitis, like the term inflammation, is used, no longer as the name of a disease, but as a term describing the anatomic lesions found in a great variety of diseases, such as tuberculosis, typhoid and infectious diarrhea. The term dysentery may be used to describe any case of infectious diarrhea in which the *Bacillus dysenteriæ* is proved to be the infecting agent. The term acute gastrointestinal intoxication is a synonym for the fermental diarrhea. It has usually been employed to describe those cases in which symptoms from the absorption of toxins are particularly prominent.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

This distinction between parasitic and saprophytic action of bacteria has the further advantage of being in line with modern effort in specific therapy. It is the infectious parasites which give rise to the formation in the body of specific immune bodies, and which, therefore, are to be combated by means of serotherapy and vaccine therapy, in which such great progress has recently been made. The saprophytes must be combated by other methods, and to present the results of the systematic investigation of one of these other methods is the purpose of the present paper. This method necessitates the recognition of the etiologic distinction suggested, and suggests the possibility, under proper fundamental etiologic distinctions, of in time arriving at the elaboration of a specific form of treatment for each of the various forms of diarrheal disease.

THE ANTAGONISMS OF BACTERIA

This method depends on the principle of the antagonism existing between various varieties of bacteria, as developed by Metchnikoff and his followers. It has been early shown that in many instances one variety of bacteria possesses the power of inhibiting the development of another, and recent literature is filled with experimental work placing the proof of this principle beyond question. It has been chiefly applied to combating fermentation in the intestine, and has been successfully applied in a great variety of diseases, particularly in chronic disturbances and in certain chronic joint conditions supposedly caused by the absorption of the toxic products of intestinal fermentation.

THE RESEARCHES OF TISSIER

My own investigations on the application of this principle to the diarrheal diseases of infancy were suggested by the work of Tissier at the Pasteur Institute in Paris.

The subject was approached by Tissier from the point of view of the organisms causing fermentation in the intestinal contents. While he does not draw a distinction between parasites in the tissues and saprophytes in the food residue, he makes no mention of organisms found in the tissues, of tissue changes, or of agglutinin formation in the blood, but does refer constantly to the chemical results of the fermentation of the intestinal contents. Moreover, the clinical type of case described by him is exactly that described in a recent classification adopted by the pediatric department of Harvard University as intestinal indigestion with fermentation, or fermental diarrhea.

Tissier made careful studies of the intestinal flora in health and in this disease, establishing characteristic bacterial pictures for each, and identifying the various micro-organisms. He finds that in health the *Bacillus bifidus* is the predominating organism of the dejecta in overwhelming predominance. In disease a bacterial transformation occurs, the *Bacillus bifidus* disappears and a number of abnormal forms appear. Tissier identified these organisms and studied them in detail, particularly their fermenting action on food elements and products. Among them he found only one variety which was pathogenic toward animals, and which attacked proteid substances and their derivatives. In doing this it forms a toxin, which has some necrotic power on the tissues. This organism is the *Bacillus perfringens*, a large rod with square ends, staining by Gram's method. In early stages it has a spore at one end; later no spores are seen. It is anaerobic, ferments sugar, and has the special peculiarity of causing solution of meat or white of egg in sealed tubes.

Tissier believes this organism to be the cause of the class of cases which we know as fermental diarrhea. The products of the fermentation caused by other organisms he regards as having a possible contributive action through irritation of the mucosa. As predisposing causes he believes that lack of digestive power and unsuitable chemical composition of the food play the chief rôles. The predominance of this disease in artificially fed infants may be attributed to the excess of proteid in cow's milk, causing more unutilized proteid to pass into the intestine. He further noted that in recovery a very rapid change occurred in the bacterial content of the discharges. The abnormal forms disappear, and the *Bacillus bifidus* reappears, at first in its bifurcated form, and quickly resumes its place as [illegible] micro-organism. He found that in [illegible] a sufficiency of carbohydrate the *Bacillus bifidus* inhibits the growth of the *Bacillus perfringens*, but that in media without carbohydrates *B. perfringens* overcomes the *B. bifidus*.

Tissier concludes that the indications for treatment are to remove the fermenting intestinal contents by purgation and to cause a reappearance of the normal intestinal flora. The latter object can be furthered by diminishing the proteid and increasing the carbohydrate in the food, and can be more specifically attained by introducing into the intestine an organism tending to inhibit the growth of abnormal forms and to overcome them and cause their disappearance. In searching for a suitable organism for this latter purpose, he found that the *Bacillus bifidus* and the lactic acid bacillus both stop the development of *B. perfringens*, and he selected the latter, as it is more easily cultivated and handled than the former, which is anaerobic. He used this organism to effect a transformation of the intestinal flora.

In cases of fermental diarrhea, Tissier gave his patients pure cultures of the lactic acid bacillus, and under this treatment he noted a rapid transformation of the stools, subsidence of the symptoms and gain in weight.

This method of treatment struck me as being in the line of advance, as it is a specific treatment directed toward specific etiology, and based on scientific research. We are apt too long to neglect to apply in practice the knowledge given us from time to time by those engaged in scientific research. We had for a long time been accustomed to combating fermentation by purgatives, starvation, lavage of the colon, and regulation of the feeding. Intestinal antiseptics have not proved of value. Yet, although the fact that the growth of one organism inhibits that of another had long been known, it had not been applied in practice in cases of intestinal fermentation. It had never occurred to us to try to stop intestinal fermentation by introducing an inhibiting organism into the intestine—a procedure of very obvious possible value. This method of treatment as evolved by Tissier step by step to its logical conclusion proved very fascinating, and I determined to test it in practice.

Whether or not all Tissier's conclusions are justified does not affect the main issue. These processes may or may not be caused by the *Bacillus perfringens* or by other organisms. We do believe them to be caused by bacterial fermentation, and we are justified in introducing into the intestine any harmless organism that affords a hope of inhibiting the abnormal processes. The lactic acid bacillus is harmless. Tissier has shown that it inhibits the *Bacillus perfringens* in the test tube, and gives evidence that it effects a transformation of the flora in the intestine. Bienstock has shown that it prevents the putrefying action of the *Bacillus putrificus*. Therefore, it at least held forth a prospect of good results.

PRELIMINARY INVESTIGATION

I began my work on this subject in the autumn of 1905, confining my researches at this time to the bacterial examination of the dejecta in various types of diarrhea. This work was neither thorough nor complete, but the results, so far as they went, agreed with those published by Tissier.

In the beginning of the summer of 1906, I commenced a systematic investigation of the clinical results of this method of treatment in infantile diarrheal disease. This investigation I have continued ever since, whenever opportunity afforded, and am still engaged on it. My summer service in the out-patient department of the Infants' Hospital afforded a large material for this work, and I had the further advantage of Dr. Rotch's permission to carry on the work during his autumn service in the wards of the same hospital.

It occurred to me that buttermilk was made with lactic acid bacilli, and that an unpasteurized buttermilk should contain large numbers of this organism. Buttermilk had been widely advocated and employed in infant feeding, but, so far as I know, never on account of its bacterial content. It had been employed for chemical reasons, because its chemical composition was believed to be adapted to certain abnormalities of digestion and metabolism. In Europe it is invariably cooked before being given to infants, and in this country, so far as I know, had always been carefully sterilized or pasteurized. Consequently, none of the literature on buttermilk is of value as bearing on the question of the action of lactic acid bacilli in fermental diarrhea. Wurtz recommends it in cases of proteid and fat intolerance; von Rommel believes its acidity to be the active principle of its favorable action; Decherf believes it to be of wide value in gastroenteritis and rachitis, and prepares it by boiling with cane sugar. And there are many other recent articles on the great value of buttermilk as an infant food, usually in cases of chronic indigestion or atrophy. Other observers have not obtained such favorable results. It had been given a thorough trial, in a pasteurized form, in Boston, without notable favorable results. I believe that its favorable action is dependent on the proteid or fat intolerance so commonly observed, and have never seen a patient who did well on pasteurized buttermilk who did not also do well on proper milk modification.

I selected buttermilk as a convenient vehicle for giving lactic acid bacilli, in the first place, because it seemed to me that in that way, by combining medicine and food, I could introduce larger numbers of the organism than if I used small doses of bouillon cultures in addition to the food. In the second place, I wished to use a constant food in all my cases, and selected buttermilk as being a digestible food, not liable to produce accidental upsets from proteid or fat intolerance.

At this time I did not know, what later investigations have suggested as very probable, that the results depend on the particular strain of lactic acid bacillus employed. It was, therefore, more or less a matter of chance that an effective strain of the lactic acid bacillus was hit on in my preliminary work.

The buttermilk selected was first pasteurized to kill all other organisms, then inoculated with a pure culture of lactic acid bacilli, and ripened until the development of the organism had brought about the proper acidity and precipitation of the casein. The particular strain of lactic acid bacilli employed was isolated by Mr. S. C. Keith, bacteriologist with H. P. Hood & Sons, who selected it on account of the delicate aroma it produces.

I was unable to carry on proper bacteriologic investigations of the stools, confining myself to the study of the clinical results.

The results of the preliminary trial of this method of treatment were exceedingly striking. The unpasteurized buttermilk was first tried in 35 selected cases. Of these, there was evidence of a favorable result, as shown by a change in the character of the dejecta and by gain in weight, in 23. In 3 cases there was immediate cessation of diarrhea and favorable change in the character of the dejecta, without gain in weight. In 9 cases the lactic acid bacilli produced no effect.

CLINICAL PICTURE OF FERMENTAL DIARRHEA

Before describing the details of these results, it is perhaps necessary to describe the clinical picture presented in these cases in which the bacterial fermentation of saprophytes in the intestine is the principal etiologic factor. These cases are characterized by diarrhea, usually of sudden onset. The movements are loose, often very watery, are usually, but not always, green in color, have a foul or sour odor, and at times are frothy. Curds and mucus may or may not be present in addition. Blood is absent, and mucus is not extensive, except in cases of long standing. Very characteristic is the absence of persistent fever. The temperature may be high in the first twenty-four or forty-eight hours, but usually quickly falls after the diarrhea becomes thoroughly established; in very severe cases, or in long-standing cases, it is frequently subnormal. Vomiting is present in the majority of cases, and is often obstinate and severe. Colic may be present, but abdominal tenderness is almost invariably absent. There is rapid loss of weight. In severe, or long-standing cases, and in babies who have had repeated attacks, there is frequently an extreme degree of atrophy and inanition. In the severe cases are seen various toxic nervous manifestations, ranging all the way from slight apathy to convulsions and collapse.

In the majority of the cases the buttermilk was begun only after all ordinary and routine measures had failed. The work from the first was made as far as possible experimental. In the treatment of this disease there are always a certain number of cases which prove refractory, and which resist the employment of all the resources at our disposal. I endeavored, so far as possible, to select such cases for experiment with living lactic acid bacilli.

The routine employed in cases of fermental diarrhea was the following: The child was first given castor oil or calomel to empty the bowel, and nothing but boiled water was given for a period of twenty-four hours. Only barley water was given for a second twenty-four hours, and then feeding with a weak milk modification, usually fat 2, sugar 5, proteids 0.25, was begun. If there were no return of symptoms, the strength of the milk was gradually increased, beginning with an increase in the percentage of whey proteid only, such as fat 2, sugar 5, whey proteid 0.90, caseinogen 0.25. Later the other elements were increased until a satisfactory gain in weight was maintained. If, however, the resumption of milk feeding was followed by a return of the symptoms, and further loss of weight, the same process was repeated, milk being this time withheld longer, at least seventy-two hours. Bismuth and irrigation of the colon were also tried, and milk feeding was finally resumed in the form of whey, to be gradually strengthened. If after this treatment the symptoms did not improve after a reasonable time, the strength of the milk was increased, as I have found that by so doing a certain number of cases will gain weight in spite of the persistence of the symptoms of fermentation. If this failed, the case came into the category of obstinate and resistant cases, and was usually treated by alternating in turn the percentages of the various elements, by cereal diluents, by peptonizing, or by resorting to a wet-nurse. It was such resistant cases which were selected for the experiment with living lactic acid bacilli. The immediate improvement, alteration in movements, and gain in weight seen in so large a number of such cases were consequently all the more striking.

The number of cases in this preliminary investigation, made so far as possible under conditions designed to be experimental, was thirty-five.

Not all of the 35 cases were of the fermental type; 5 cases were diagnosed as of the irritative type of acute intestinal indigestion, and were selected for trial merely for experimental purposes. None of these 5 showed improvement. Two of the cases in the series were of the infectious type, probably of dysenteric origin, characterized by persistent fever and bloody mucous stools. In both of them, also, the unpasteurized buttermilk failed to bring about any notable change.

Thus only 2 of the cases of total failure were frankly of the fermental type of disease, the type described by Tissier. Consequently, if the fermental cases alone be considered, the figures are as follows: Treatment successful, 23 cases; partly successful, 3 cases; failed, 2 cases. In the 23 successful cases, the use of the living lactic acid bacilli was followed, not only by cessation of diarrhea and the signs of fermentation in the dejecta, but by rapid gain in weight. In the 3 partly successful cases, the signs of intestinal fermentation rapidly disappeared, but there was no notable gain in weight while the patients continued under observation.

PROOF OF SPECIFIC ACTION

In order to be able to justify the conclusion that these favorable results were due to the action of the living lactic acid bacilli, it was necessary to obtain evidence that they were not due to the chemical qualities of the buttermilk as a food. Such evidence is particularly necessary in view of the many reports of the favorable action of buttermilk referred to above. To investigate this, in fourteen resistant cases of the fermental type, the buttermilk was first given in a pasteurized form, and after a sufficient trial had demonstrated a failure to cause improvement the pasteurization was simply omitted, no other change being made. In every one of the cases the omission of the pasteurization was followed by immediate improvement. When it is remembered that these were all cases in which, under routine treatment, the babies had failed to show improvement, and that they had also failed to show improvement when fed on pasteurized buttermilk, I think I am safe in concluding, in so far as conclusions may be drawn from mere clinical experience, that the favorable change was not due to the chemical peculiarities of the food used, but was due to the only new element added to the treatment, which was the introduction of large numbers of living lactic acid bacilli into the intestine through the omission of the pasteurization.

FINAL STATISTICS

So favorable were the results of the treatment that I determined no longer to confine its use to resistant cases, but to use it as a regular weapon in the treatment of diarrheal disease. I have used it in several hundred cases. Many of the babies were out-patients, and did not return to the hospital often enough to permit the completion of the records. I was able, however, to collect fairly complete records of 120 cases. In all of these cases the treatment was with some milk preparation ripened with lactic acid bacilli, without subsequent pasteurization. Not all the babies were treated with unpasteurized buttermilk, in which the fat is removed by churning after the ripening; but many were treated with various formulas of modified milk similarly ripened. The statistics of these cases are as follows: Treatment successful, 78 cases; partly successful, 12 cases; failed, 30 cases.

Not all of the one hundred and twenty cases were of the fermental type. Twelve cases were diagnosed as of the irritative type of disease, and these cases were selected for trial only because they proved resistant to the routine treatment, or because the condition of the child was so serious as to warrant trying whatever held out any promise of doing good. As the two types run into one another, the element of fermentation often being found in cases of the irritative type, I hoped that, in view of the remarkable results which I was obtaining in the frankly fermental cases, I might be able to do good in these resistant irritative forms. This hope was disappointed. Every one of the twelve cases of the irritative type in which the buttermilk was used is numbered among the failures. This result was all the more significant in contrast with the similarly resistant fermental cases, and is evidence in favor of the specificity of this method of treatment.

Eight of the cases in the series were of the infectious type, but were selected because there were evidences of fermentation in the intestinal contents, in addition to infection of the tissues. In 4 of these cases, the patients had failed to gain after the acute stage of the disease had subsided, but later the use of the living lactic acid bacilli was immediately followed by Tissier's so-called "transformation of the stools" and by gain in weight. In the other 4 infectious cases, no good result followed the use of the treatment.

Taking the frankly fermental cases, the figures are as follows: Treatment successful, 74 cases; partly successful, 12 cases; failed, 14 cases.

CLINICAL EFFECTS OF THE TREATMENT

The principal result of this treatment, when successful, is the bringing about of what Tissier calls a "transformation of the stools." The character of the dejecta changes, frequently in the most remarkable way, from loose, foul and green, to formed, pale yellow, with a sour odor. The typical lactic acid stool is of rather firm consistency, is light yellow, or white and putty-like, and has a rather agreeable sour odor. With the cessation of the diarrhea, the toxic symptoms disappear, vomiting ceases, and the child becomes happy and comfortable. At times the sour milk is vomited at first, but this rarely lasts more than one or two days. In the most successful cases, gain in weight is rapid.

OCCASIONAL UNSUITABILITY OF RIPENED MILK AS FOOD

Not by any means in all of the successful cases were the babies able to gain weight on the ripened milk alone. In about 50 per cent. of the successful cases the children gained, for a time at least, while taking this food only. There were cases in which the use of the unpasteurized buttermilk was followed by immediate improvement in the symptoms and discharges, but in which a gain in weight did not follow. When, however, the buttermilk feeding was supplemented by alternate feedings of modified milk, steady gain in weight began at once. These cases suggested that, although the lactic acid bacilli had stopped the fermentation, the buttermilk was not adapted to the caloric needs of the child. When the buttermilk was supplemented with food of higher caloric value, the child gained weight. The lactic acid bacilli having prepared the way by causing a cessation of fermentation, the patient was able to thrive on a formula which in the first place it could not digest. In similar cases, the buttermilk was only continued until the alteration in the movements had occurred, and then the child was put back on the same food on which it had done badly before the use of the buttermilk. In such cases, after the buttermilk had been used, the patient gained weight. Thus the ripened milk was used only as a medicine against the fermentation, to be omitted when it had accomplished its work. In some cases in which unpasteurized buttermilk was used, in which there was no gain in weight, the food appeared, not so much of deficient caloric value, but rather as an irritant, causing gastric or intestinal indigestion. In these cases, it was similarly used merely as a temporary weapon against the saprophytic fermentation.

USE OF BOUILLON CULTURES

In four cases of this type, in which ripened milk could not be digested, the method of giving pure bouillon cultures of lactic acid bacilli was employed, as originally advocated by Tissier. In all four of these cases there was the characteristic change in the *dejecta*, but in only one of them was there subsequent gain in weight. I think this method of treatment is to be recommended in those cases in which ripened milk causes serious symptoms of indigestion.

RIPENING OF MODIFIED MILK MIXTURES

The fact that buttermilk as a food is not always adapted to the digestive and caloric needs of individual infants suggested the possibility of another method of employing living lactic acid bacilli in the treatment of this class of cases. A certain amount of fat in the food may be necessary for a particular infant, on account of the high caloric value of this food element, and the existence of this fermental diarrhea does not imply the existence of fat intolerance. On the other hand, the high proteid content of buttermilk may cause indigestion in babies of special susceptibility to proteid. If it is possible to grow lactic acid bacilli in buttermilk, it is also possible to grow them in other percentage modifications. We can thus combine the two indications for treatment by giving the food suited to the digestive and nutritive requirements of the infant and by stopping fermentation; and can also combine the resource of living lactic acid bacilli with the wide range of resources afforded by percentage feeding, by ordering the various mixtures which we believe adapted to the need of individual cases to be ripened with lactic acid bacilli.

With this end in view, I arranged with the Walker-Gordon Laboratory that on order they would inoculate and ripen any percentage formula with lactic acid bacilli. Under this arrangement the physician only has to select the formula which he believes to be most favorable for the individual case and write a prescription to the laboratory, as, for example: fat 2, sugar 5, whey proteid 0.90; caseinogen 0.25, lime water 5, ripened with lactic acid bacilli.

This experiment has by no means proved to be a complete success. It soon appeared that the various modified milk formulas, when thus ripened, were not well digested. The fat in such formulas, after ripening, tended to separate out and float on the top of the bottle in the form of liquid butter. This is not a suitable food for these babies. In view of this, I soon found that I was obliged to confine my work to formulas containing no fat. Fat-free milk ripened with lactic acid bacilli was the food employed in the majority of the later cases in the series. When made from whole milk and undiluted, this food amounts to about the same thing as buttermilk, the difference being that in buttermilk the fat is removed by churning after the milk is ripened, and in the fat-free milk the fat is removed by centrifugalization before ripening. It is possible to vary the percentages of proteid and the milk sugar, and in this way the resources of percentage feeding may be in part employed in cases which present peculiarities of digestive power and requirements. Many patients, however, take the ripened fat-free milk undiluted without indigestion. In those cases in which this food is insufficient in caloric value, it may be alternated with a modified milk formula in which there is fat, or it may be used temporarily as a medicine only.

Later work conducted by Mr. Howe, of the Walker-Gordon Laboratory, has shown that if the milk is properly ripened, formulas may be used which contain fat as high as 1 per cent. without the fat separating out. I have as yet had no clinical experience in the use of such formulas.

VARIATIONS IN THE EFFECTS OF DIFFERENT STRAINS OF LACTIC ACID BACILLI

Metchnikoff and other foreign investigators have pointed out that the lactic acid bacillus as a species is subdivided into many different strains which are not all of equal value in combating fermentation and putrefaction. I have been able in part to confirm this observation as applied to intestinal fermentation in infants. I have found that strains of lactic acid bacillus isolated from other sources did not appear always to give such good results as the strain of which I originally hit on by chance. My figures are too few to afford absolute proof of this fact, but I think it very probable that in the use of living lactic acid bacilli to combat fermentaton it is necessary to select a strain of good or proved value. I think that some of the failures which have been reported from this method of treatment may possibly be due to the fact that different strains have been employed. For instance, I have found during the last summer that Hood's buttermilk, when given unpasteurized, did not produce such good results as it had in previous summers, nor did it in general give such good results as the ripened fat-free milk prepared at the Walker-Gordon Laboratory from the original strain. I do not know whether the strain of the lactic acid bacilli now employed in Hood's Laboratory is the same as that employed in previous years, but I do know that there have been changes in their laboratory, and that Mr. Keith is no longer their bacteriologist. Recently we have received in Boston from Bulgaria Metchnikoff's own strain of the lactic acid bacilli, which has proved of value in combating fermentation. During the coming summer there will be a sort of contest between the home product and the importation from Bulgaria to determine which is the more effective.

THE USE OF THE LACTIC ACID BACILLUS IN PRACTICE

In practice, when it is desired to employ this treatment of living lactic acid bacilli, the physician may use buttermilk from some dairy, giving it unpasteurized, or he may prepare his own ripened milk with a culture of the lactic acid bacillus obtained from the nearest dairy. The objection to obtaining the bacillus in this way is that it is a matter of chance whether or not an efficient strain of the organism is hit on. It is possible that the buttermilk, or culture, so obtained, may be of the highest efficiency, and, on the other hand, it is possible that it may have but little power against saprophytic fermentation. It is better to obtain a culture of proved value for use in those places where laboratory feeding is available; the culture may be kept in the milk laboratory, and the ripened milk may be ordered from there. When laboratory feeding is not available, or is not desired, the physician may prepare his own ripened milk in the following manner: He should first send for a bouillon culture of an efficient strain of the organism. Such strains may now be had certainly at the Walker-Gordon Laboratory in Boston, and possibly at other places. The cream is removed as far as possible from the milk, and then the skimmed milk is inoculated with the lactic acid culture. The inoculated milk is then kept in a warm place until enough acidity develops to sour the milk or to produce a very fine curd, when the milk is set aside and kept on ice for use. Some of this milk is set aside each day, to be used as a culture for inoculating the next day's supply, and in this way the strain of lactic acid bacillus may be perpetuated indefinitely, as it apparently has the property of killing out accidental contaminating organisms. The artificial tablets of the lactic acid bacillus, such as the lactone tablets and similar products, make excellent buttermilk for mere feeding purposes, but are not advisable when the purpose is to give as many as possible of the living bacilli.

INDICATIONS FOR AND LIMITATIONS OF THE USE OF LIVING LACTIC ACID BACILLI

The results of my investigation on the action of living lactic acid bacilli have led me to conclude that it is of great value in the class of infantile diarrheas designated as fermental. The numerous variations in the series show that it is not absolutely a specific treatment. It is possible that these failures may be attributed to the fact that the particular strain of lactic acid bacillus used is not effective against the particular strain of fermenting organisms concerned. It is probable that there are also many other elements tending toward failure of which we know nothing. I believe, however, that this treatment is an extremely valuable resource, and one which is applicable to a very difficult class of cases. I believe that it should be tried in every case of infantile diarrhea characterized by saphrophytic fermentation, and in every case of chronic intestinal indigestion and atrophy in which the movements are characterized by evidences of fermentation. I believe a ripened milk containing living bacilli to be the best food with which to begin feeding in cases of fermental diarrhea after the initial period of starvation.

ABSTRACT OF DISCUSSION

Dr. J. P. Crozer Griffith, Philadelphia: I have no doubt that Dr. Dunn has employed the best milk in his preparation, but in country districts, where it is not possible to obtain the cleanliness desired, would he feel justified in trusting that the growth of lactic acid bacteria would do away with the necessity of pasteurizing? I am a great believer in the use of buttermilk, but I have always heated it after it has been made. What, too, in the ordinary nomenclature, would Dr. Dunn call this lactic acid germ? There are many different germs, various in name, which are capable of producing lactic acid.

Dr. Elias H. Bartley, Brooklyn: There are about twenty-five or more different kinds of lactic-acid-producing bacilli. What particular one does Dr. Dunn consider the best? I have had failures and I can readily understand from the statements made that some lactic-acid bacilli are satisfactory and that others are absolutely worthless. For the treatment of this fermentative diarrhea we must have a suitable strain. This being the case, it is important that we know what strain to select or where we can get it. I think Dr. Dunn was exceedingly fortunate, as he says, in happening to hit on a satisfactory strain in his experiments. That might happen to any one of us, but the accident is much more likely to be in the other direction of getting a wrong strain. It seems to me that the value of the paper lies in reducing what has been a haphazard practice to a scientific one. Has Dr. Dunn had any difficulty in getting children to take the ripened milk? I have had that difficulty in feeding children on buttermilk. Babies do not seem to like it and after a few days refuse to take it. Again, Dr. Dunn says that in some cases the children were not improved and in some cases they were even made worse. Could he determine beforehand which cases were suitable for this treatment and which were unsuitable?

Dr. Thomas Morgan Rotch, Boston: From time to time great advances are made in the milk laboratories in just such questions as this. One of the latest laboratory discoveries is how to make the curdled milk fine enough to go through the nipple, which is the most practical point. These are not infectious cases but are due to the action of the saprophytes. They are simply fermentative forms of diarrhea, but there is no true infection in the cases in which the lactic-acid bacillus is an important factor in their relief. Now as to the separation of the strain; two years ago in Stockholm, I met Professor McGee, the most prominent Scandinavian physician. They have made great advances there in the use of buttermilk and Dr. McGee said that they had the very best buttermilk in the world: but he had found that some years it would act satisfactorily and another summer it would not. Dr. McGee came over here to see what Dr. Dunn was doing and he has taken back with him some of this strain with which Dr. Dunn has been working. We do know that this strain which Dr. Dunn has differentiated is the most satisfactory obtainable. The fact that a physician does not have success with the treatment does not prove that the method is a failure because, in the first place, he must have the especial type of case to treat and then he must have the especial strain of bacillus for the treatment.

Dr. John Lovett Morse, Boston: I wish to call attention to a paper read before the American Pediatric Society in 1905 by Dr. H. T. Bowditch and myself, the title being "Certified Milk in Infant Feeding." In it, many of the points brought out to-day were covered. I am sorry to disagree with my colleagues. I have, however, treated the babies in the same hospital with the same buttermilk, with skim milk "ripened" with the same strain of the lactic-acid bacillus and with mixtures ripened with the same strain and have not obtained the same results as did Dr. Dunn. My experience is that the results from buttermilk and from milk mixtures "ripened" with the lactic-acid bacillus are no better than those obtained from other milk mixtures of the same chemical composition. The results are the same whether the buttermilk is pasteurized or not. In a certain number of cases, however, the results are striking. In these cases they are probably due to the change in the bacterial flora. If the lactic-acid bacilli have this favorable action in suitable cases, they should have just as unfavorable an action in unsuitable cases. At present I doubt if we are able clinically to determine in advance what children will be helped and what injured by this treatment. It seems to me, therefore, that until we have some method for the rapid bacteriologic examination of the stools we certainly can not use this method of treatment intelligently and perhaps not even safely.

Dr. Frank P. Gengenbach, Denver: I had the pleasure of spending nearly a year in Finkelstein and Heubner's clinics in Berlin, and they feel that the feeding of buttermilk derives its value from its chemical composition and the low fat percentage, and they also believe that the diarrhea is due simply to indigestion and not to the bacteria and that when you remedy the indigestion by a starvation process and then build up the nutrition you have met the indications. They have secured the same results by the use of pasteurized buttermilk that Dr. Dunn has obtained from the use of non-pasteurized buttermilk.

Dr. T. M. Rotch, Boston: There is no question but that after a baby has had an attack of this condition that we suppose is due to the saprophytes, the intestine becomes so vulnerable to irritation that other organisms will take hold very readily. After a child has been infected one can still go on with the lactic-acid bacillus and though one can not get at the organisms that have gotten into the tissues, at least it is better to continue the lactic acid, thus taking care of the saprophytes that are present in the intestinal tract and at the same time supporting the child thereby.

Dr. LeGrand Kerr, Brooklyn: What was the longest time that any particular infant was fed on these mixtures? Following the time that the child was fed on these mixtures was there any subsequent disturbance?

Dr. C. H. Dunn: I did not go into all the different statistics as to the names of the various strains of this bacillus. There is an immense number of strains. Each dairy has its own strain which it selects on account of the aroma it imparts to the butter. I tested the strains from a number of dairies until I got a strain that had the particular action desired. This strain has not yet been given a name. Another satisfactory strain is the Bulgarian. There are doubtless other good strains. In reply to Dr. Griffith, I would certainly not rely on the bacilli to counteract unclean milk. In every case milk is very carefully pasteurized to clear it of other organisms and it is then ripened. Two things are involved in the treatment of fermentative diarrhea, one being the removal of the fermentation and the other the feeding of the baby. In order to meet the last condition it is absolutely necessary to take into consideration the baby's peculiarities of digestive powers and requirements. These two things must go together to get success. I know that many physicians have believed that babies could be put on a fat-free food and kept on it indefinitely, but I have seen cases in which a baby with this form of diarrhea was kept on this food for one day and then was put back on its regular food and got along well. This is a suitable method of treatment in those cases showing symptoms of autointoxication when there are green stools, etc. Cases characterized only by undigested food in the stools are not suitable for this method. Only those babies having greenish, loose stools should be put on this treatment. The very title of Dr. Morse's paper, "Acidified Milk in Infant Feeding," shows that he does not quite grasp what I mean. The feeding in these cases must be distinguished from the specific treatment of the fermentation. When one speaks of buttermilk in infant feeding it is an entirely different matter. I am perfectly willing to grant the value of buttermilk feeding in cases of fat intolerance. In these cases pasteurized or non-pasteurized buttermilk has proved of great value, but this has nothing to do with the specific action of the lactic-acid bacillus. I believe you will find that giving a bouillon culture of a good strain in suitable cases will give as good results as buttermilk. It is not a question of buttermilk or fat-free milk, for that is a question of the digestive powers of the child. This is merely a question of fermentation. There is no question but that in those fourteen cases the moment the pasteurization was omitted, no other step being taken, the movements changed to normal, the patients began to gain in weight and all symptoms subsided. I do not see how there could be a greater proof that this favorable result was due to the action of the living lactic-acid bacillus. I am talking merely of acute toxic cases due to saprophytic action. I have had other patients who could be fed nothing but acidified milk, but those were not cases in which the action of the lactic-acid bacillus was required, and the good result was due to the need of an acidified diet.

ADENOID HYPERTROPHY DURING THE FIRST YEAR OF LIFE AND ITS TREATMENT *

ROWLAND GODFREY FREEMAN, M.D.
NEW YORK

Although a great deal has been written concerning adenoids in children, so that competent practitioners readily diagnose them and have them removed, little attention has been paid to these growths in early infancy. In New York at least a very considerable proportion of infants have adenoids that require removal during the first year.

Adenoids, if they are to be removed at all, should be removed as soon as they produce symptoms, and especially during the first year of life, for it must be remembered that children with lymphatic hyperplasia have one of the indications of lymphatic constitution and may not be good subjects for anesthesia, while adenoids may be removed during the first year without anesthesia.

Attention should be directed to this abnormality of early infancy, as the persistence of this trouble interferes with the proper development of the child, by reflex action, by the irritation produced by its presence and by the obstruction it causes.

The postnasal pharynx at birth is a space only ¼ inch high by ⅓ inch wide so that a slight adenoid hypertrophy at this period will cause obstruction. By the end of the first year this space has increased to nearly double this size.

Adenoid hypertrophy often produces symptoms during the first days of life, that is, the mother states that the child has had snuffles from birth. Cases of this sort are sometimes diagnosticated as syphilis, but the other characteristics of syphilis at this period are lacking. A case of this sort in which the patient was receiving specific treatment came under my observation during the past winter. Becoming convinced that the symptoms were due to adenoid hypertrophy and not to specific disease, the specific treatment was discontinued and the child carefully watched for other symptoms, but nothing more developed that might be interpreted as an evidence of syphilis.

The snuffles are particularly evident when the child is nursing and may occur during sleep if the child's mouth is kept closed. If the mouth is kept open snoring replaces the snuffles.

Snuffles result from an adenoid which produces irritation, and if it becomes large enough to obstruct the postnasal pharynx we have the further symptom of mouth-breathing.

Mouth-breathing, like snuffles, may be due to other causes than adenoid hypertrophy, but most of the cases of nasal obstruction during the first year are due to adenoid hypertrophy.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

A third indication of this condition during the first year is the presence of recurrent colds. These colds have the character of a cold in the head, there being some nasal discharge and fever, and they are accompanied sometimes by a pharyngitis. These recurrent colds during the first year are usually caused by adenoid hypertrophy.

A most characteristic sign of this condition is the cough. This cough is usually of a persistent character, often without any indication in the pharynx or bronchi to account for it. In some cases it is paroxysmal and may simulate closely the paroxysms of whooping cough. A case occurred in my hospital work during the past winter. A baby of six months, weighing 10½ pounds, was presented by the house physician as affected with whooping cough. The child was very anemic and in a desperate condition, vomiting apparently practically all its nourishment and coughing continuously day and night. The removal of the adenoid in this case stopped immediately both the cough and the vomiting.

A fifth symptom of adenoids during the first year is otitis media, a complication which may produce dangerous results. One only or all of these symptoms may be present.

The determination of the presence of an adenoid in a very young infant is not as readily made on account of the very small space in the postnasal pharynx. In making this examination, as in all examinations of young children, rapid manipulation avoids resistance and disturbance.

In order to make an adenoid examination have the child held with its head against the left shoulder of the nurse, the right arm of the nurse holding the hands and her left hand holding the forehead. Then if the left thumb of the examiner is pressed against the right cheek of the child so as to bring the buccal mucous membrane between the gums, the ends of the fingers of the left hand grasping the right side of the lower jaw, a firm grip is obtained which makes it impossible for a child with teeth to bite the examiner. The right index-finger is used for passing through the mouth into the postnasal space, or, if this is too small to admit the index-finger, the little finger may be used. The rough surface of the adenoid is quickly detected by one accustomed to making this examination, which may often be completed so quickly that the child does not cry.

An acute adenoid enlargement due to a cold which was not preceded by adenoid symptoms may occasionally disappear on hygienic treatment without medicine or with the syrup of iodid of iron, with or without cod-liver oil. For a chronic enlargement, however, only one method of treatment is available, and that is the removal of the adenoid by operation.

This operation in infancy can be done quickly without an anesthetic and with very little shock to the child and no lasting fright.

For the purpose of operation an assistant is necessary to hold the child, while a nurse should be present to assist and to remain awake by the child for two nights to watch for hemorrhage.

The child should be wrapped tightly in a sheet which binds the arms to the sides and should be held upright by the assistant with the back of the head of the child against the assistant's left shoulder, one of his arms pressing against the arms of the child, the other hand pressing its forehead back against the shoulder.

A gag is first introduced which is held by the nurse, while the operator, holding down the tongue, passes a Gottstein curette to the posterior nares, bringing the blade of the instrument as far up and as far forward as possible, then first by a backward followed by a downward stroke the adenoid may be removed in one piece.

In case it is not entirely free, forceps must be used. In most cases one use of this instrument is sufficient. The child's head is then thrown forward over a basin and the hemorrhage, if profuse, is checked by the application of cold to the face, cold water, ice-water, or ice. When the hemorrhage has ceased the child is put back in the previous position, the tongue depressed, the throat examined for particles that may have been incompletely severed and the finger introduced into the postnasal pharynx to be sure that the adenoid is completely removed.

The child is then put to bed without a pillow, lying on the side with the face forward, and the nurse is supplied with a spray containing 1 to 5000 adrenalin, to be used in case of hemorrhage, in which case the child should be placed with face upward and the adrenalin sprayed through the nose.

The shock of this operation is so slight that on a number of occasions the child has been asleep, having taken its bottle as usual, before the operator left the house.

Frequently it is desirable to operate when the child is still having some fever, this being often due to a cold to which the adenoid hypertrophy is contributing. I believe that a temperature of 100 to 101 may not be a contraindication of operation, as frequently such a temperature drops to normal after the operation and does not rise again.

In some cases, owing to the desire of the parents, an anesthetic must be given. It is well in such cases to mention the possibility of a lymphatic constitution and the danger of anesthesia in that case. If an anesthetic is used it should be nitrous oxid, and only sufficient should be used to produce primary anesthesia.

As to the results of this operation, a slight increase in the snuffles may be present for a few days; rarely is there any fever or evidence of pain, while the improvement in the symptoms and in the development of the child is always most satisfactory.

In conclusion, adenoid hypertrophy which causes persistent symptoms should be operated on as early as the fourth or fifth month of life; the operation should be done rapidly and without an anesthetic.

211 West Fifty-seventh Street.

ABSTRACT OF DISCUSSION

Dr. George L. Richards, Fall River, Mass.: I have been considerably interested in this work, especially in children under 1 year of age, in whom there is difficulty in breathing at night. These children are nose breathers during the day but not at night, and in these cases the question of operating for adenoids comes up. Dr. Morse has written much on this subject and as a result of his teachings many of us watch for this condition in children who are referred to us far more than we did. In these young children it is hard to get the finger into the nasopharynx without injury and examination with the mirror is out of the question. In such cases, if the child is held before a good light, the tongue depressed and the palate lifted up with a palate retractor, a very good view of the pharynx can be obtained. The question of anesthesia or *non-anesthesia is more or less a question of the desire of the* parents. Very little anesthesia is required, but as a rule I find that the parents prefer even that little. The Gottstein curette is a good instrument, but it has one disadvantage, namely, the possibility of cutting too deep. The Shütz adenotome, and the new one devised by Dr. LaForce, of Iowa, give good results.

With either of these instruments the entire adenoid can be removed with one stroke of the blade and practically as painlessly as the ordinary examination. A small adenoid curette devised by Vogel is then used in each fossa of Rosenmüller to be sure that no adenoid is left in this situation. The one essential thing in the young child, on account of the danger of getting an infection of the Eustachian tube, is to do the operation in a good light and see the field of operation; not merely to operate by the sense of touch.

Dr. Henry L. Coit, Newark: I have generally expressed myself as opposed to operation on adenoids in children under 1 year, but Dr. Freeman's plan is reasonable and convincing. My chief objections to the operation are the danger to small infants of anesthetics, and the fact that they do not well bear the loss of blood. I would be sorry to see this matter turned over to the throat and nose men if they go after these little children as they do after some others who do not have adenoids. I recall one case of a child of 14 months who had a continuous temperature, and the physician made a diagnosis of tuberculosis due to hypertrophy in the nasopharynx. An operation was done and they did not get anything. I was called, and after disproving tuberculosis, found that the child had never been weaned and was taking nothing but milk with still 7 per cent. sugar. There were malodorous stools, and besides this the child had indulgent parents and grandparents. I felt sure that faulty feeding was the cause of its malnutrition and fever. It was not a difficult feeding case, but a case of easy feeding with difficult parents and grandparents. A trained nurse was ordered for the purpose of hypnotizing the parents and weaning the baby and there was no further trouble.

Dr. John Lovett Morse, Boston: The members of the section probably remember that I read a paper on this subject two years ago. I want to exphasize again the fact that the symptomatology of adenoids in infancy is not that of adenoids in childhood. The symptoms in infancy are snuffles, repeated "colds," irritating cough at night, difficulty in nursing and otitis media. I believe that adenoids should be removed whenever they cause symptoms, no matter how young the baby is. I have seen them cause symptoms in babies only a few weeks old. I do not operate myself, because I believe that the operation demands the skill of a specialist. I disagree entirely with Dr. Coit and think that the operation should be performed by a man who is in the habit of doing these operations. I do not find that the specialists are unduly anxious to operate; in fact, my difficulty in Boston is to find men who are willing to operate on these babies for me. They object to operating on young patients and it is very difficult to make them appreciate how much harm adenoids may do in infancy. It is not recognized how frequently otitis media in babies is due to adenoids. A baby may have repeated attacks although the adenoids are very small. In fact, it is possible to overlook them in these cases unless a very careful examination is made.

Dr. Frank S. Churchill, Chicago: I do not think there is any danger of the throat and nose men operating too often. My experience also has been that they are afraid to operate on these babies. I have had difficulty in getting them to operate even when it is clearly shown that there are marked symptoms of adenoids. Unless there is something very urgent about adenoids or hypertrophied tonsils, I always like to have them operated on during the late spring or early summer, when the children will have time to recuperate before the winter. My experience has been that when operated on late in the fall the children are apt to have as many colds during the ensuing winter, or even more of them, than before the operation was done. It is hard to convince the nose and throat men of the fact because they do not see the children afterward. We do. That is a point on which I think the nose and throat men need education. As to a temperature of 100 of 101 F. being an indication for the removal of adenoids, I would want to be very sure as to what that temperature is due before having an operation done. I should want to watch the baby carefully for several days and make many cultures before subjecting it to an operation.

Dr. D. J. M. Miller, Atlantic City: I think that much of the odium that has fallen on this operation has been due to the fact that these patients have been so often subjected to an operation by some one not skilled in the work. I am much opposed to the general practitioner performing such an operation. When these symptoms occur in very young babies, it seems to me that the milder cases can be cured without operative interference by the continued use of a weak solution of iodin in glycerin, and by the use of antiseptic sprays. I have seen babies recover entirely under this treatment.

Dr. S. W. Kelley, Cleveland: As has been said, whatever the physician may wish, the question of anesthesia is often decided by the parents. If it is left to me I do not use an anesthetic when operating on infants. For this I have sometimes been criticized as cruel. In other cases the parents positively will not allow the use of an anesthetic. In operating without anesthesia a sitting posture is to be preferred. As to the manner of holding the patient, instead of having a sheet wrapped tightly about the chest and the nurse holding the patient over the arms with one hand and with the other hand holding the head of the patient, I prefer to have the nurse seated, reaching around from behind, hold the patient by the wrists, one in each hand, the patient's arms being crossed in front; and have an assistant, standing behind, hold the child's head between his hands, at the same time retaining the gag in place, unless a Whitehead gag is used. I object to scraping and crushing instruments, and prefer a sharp curette or one of the forms of guillotine.

Dr. W. D. Ludlum, Brooklyn: One point barely referred to is the question of recurrence. In my judgment these babies operated on very early, even when the operation is thoroughly done, sometimes have recurrences, and that I think is the reason of the indisposition on the part of specialists to operate even up to 2 years of age.

Dr. S. M. Hamill, Philadelphia: I am not ordinarily ultraconservative, and in a general sense I agree with what Dr. Freeman has said. If I understood him correctly, he does not operate in every case of adenoids, but only in those cases in which there is some evidence of obstruction or some definite interference with health. Of course, when there is some indication, I approve of the operation, but the idea of operating in every case of adenoid swelling, which may be but temporary, or on every child with otitis media merely because one thinks there may be some slight enlargement of the pharyngeal tonsil, as has been advocated, I believe to be wrong. I agree that the symptomatology of adenoids in early life differs from that in older children, but these symptoms are frequently only temporary and will disappear without operation, and unless the indications are very definite, I do not approve of operation during the first year. I believe also that, aside from the child, we have no right to subject the parents to the shock of any operation on an infant, which may be of questionable value.

Dr. R. G. Freeman, New York: As to temperature being a contraindication to operation, a persistent temperature of from 100 to 101 F., apparently due to the presence of the adenoid, is best eliminated by removing the adenoid. Recurrence of adenoids is due largely to the predisposition on the part of the child to produce adenoid tissue and not to defective operation, and it might well be questioned whether, if it were possible, it would be good policy to remove all adenoid tissue. It is, however, necessary to eliminate obstruction and irritation due to large adenoids.

Changes in the Hypophysis During Pregnancy.—Erdheim and Stumme have recently published an extensive monograph on this subject (G. Fischer, Jena), reporting research at Weichselbaum's Pathologic Institute at Vienna. The findings in 122 cases are classified. The hypophysis seems to increase in size and weight during pregnancies until it becomes permanently enlarged. The average weight in the multiparæ was 1.06 gm., with 0.81 gm. as the minimum, while the average for the primiparæ was 0.83 gm., with 0.65 gm. as the minimum. Some of the physical signs hitherto ascribed to the pregnancy are probably the result of this hypertrophy of the hypophysis, such as the swollen face, lips and hands sometimes observed toward the close of a pregnancy. A tendency to adenomatous hyperplasia was observed in fully 10 per cent. of the hypophyses examined.

A third indication of this condition during the first year is the presence of recurrent colds. These colds have the character of a cold in the head, there being some nasal discharge and fever, and they are accompanied sometimes by a pharyngitis. These recurrent colds during the first year are usually caused by adenoid hypertrophy.

A most characteristic sign of this condition is the cough. This cough is usually of a persistent character, often without any indication in the pharynx or bronchi to account for it. In some cases it is paroxysmal and may simulate closely the paroxysms of whooping cough. A case occurred in my hospital work during the past winter. A baby of six months, weighing 10½ pounds, was presented by the house physician as affected with whooping cough. The child was very anemic and in a desperate condition, vomiting apparently practically all its nourishment and coughing continuously day and night. The removal of the adenoid in this case stopped immediately both the cough and the vomiting.

A fifth symptom of adenoids during the first year is otitis media, a complication which may produce dangerous results. One only or all of these symptoms may be present.

The determination of the presence of an adenoid in a very young infant is not as readily made on account of the very small space in the postnasal pharynx. In making this examination, as in all examinations of young children, rapid manipulation avoids resistance and disturbance.

In order to make an adenoid examination have the child held with its head against the left shoulder of the nurse, the right arm of the nurse holding the hands and her left hand holding the forehead. Then if the left thumb of the examiner is pressed against the right cheek of the child so as to bring the buccal mucous membrane between the gums, the ends of the fingers of the left hand grasping the right side of the lower jaw, a firm grip is obtained which makes it impossible for a child with teeth to bite the examiner. The right index-finger is used for passing through the mouth into the postnasal space, or, if this is too small to admit the index-finger, the little finger may be used. The rough surface of the adenoid is quickly detected by one accustomed to making this examination, which may often be completed so quickly that the child does not cry.

An acute adenoid enlargement due to a cold which was not preceded by adenoid symptoms may occasionally disappear on hygienic treatment without medicine or with the syrup of iodid of iron, with or without cod-liver oil. For a chronic enlargement, however, only one method of treatment is available, and that is the removal of the adenoid by operation.

This operation in infancy can be done quickly without an anesthetic and with very little shock to the child and no lasting fright.

For the purpose of operation an assistant is necessary to hold the child, while a nurse should be present to assist and to remain awake by the child for two nights to watch for hemorrhage.

The child should be wrapped tightly in a sheet which binds the arms to the sides and should be held upright by the assistant with the back of the head of the child against the assistant's left shoulder, one of his arms pressing against the arms of the child, the other hand pressing its forehead back against the shoulder.

A gag is first introduced which is held by the nurse, while the operator, holding down the tongue, passes a Gottstein curette to the posterior nares, bringing the blade of the instrument as far up and as far forward as possible, then first by a backward followed by a downward stroke the adenoid may be removed in one piece.

In case it is not entirely free, forceps must be used. In most cases one use of this instrument is sufficient. The child's head is then thrown forward over a basin and the hemorrhage, if profuse, is checked by the application of cold to the face, cold water, ice-water, or ice. When the hemorrhage has ceased the child is put back in the previous position, the tongue depressed, the throat examined for particles that may have been incompletely severed and the finger introduced into the postnasal pharynx to be sure that the adenoid is completely removed.

The child is then put to bed without a pillow, lying on the side with the face forward, and the nurse is supplied with a spray containing 1 to 5000 adrenalin, to be used in case of hemorrhage, in which case the child should be placed with face upward and the adrenalin sprayed through the nose.

The shock of this operation is so slight that on a number of occasions the child has been asleep, having taken its bottle as usual, before the operator left the house.

Frequently it is desirable to operate when the child is still having some fever, this being often due to a cold to which the adenoid hypertrophy is contributing. I believe that a temperature of 100 to 101 may not be a contraindication of operation, as frequently such a temperature drops to normal after the operation and does not rise again.

In some cases, owing to the desire of the parents, an anesthetic must be given. It is well in such cases to mention the possibility of a lymphatic constitution and the danger of anesthesia in that case. If an anesthetic is used it should be nitrous oxid, and only sufficient should be used to produce primary anesthesia.

As to the results of this operation, a slight increase in the snuffles may be present for a few days; rarely is there any fever or evidence of pain, while the improvement in the symptoms and in the development of the child is always most satisfactory.

In conclusion, adenoid hypertrophy which causes persistent symptoms should be operated on as early as the fourth or fifth month of life; the operation should be done rapidly and without an anesthetic.

211 West Fifty-seventh Street.

ABSTRACT OF DISCUSSION

Dr. George L. Richards, Fall River, Mass.: I have been considerably interested in this work, especially in children under 1 year of age, in whom there is difficulty in breathing at night. These children are nose breathers during the day but not at night, and in these cases the question of operating for adenoids comes up. Dr. Morse has written much on this subject and as a result of his teachings many of us watch for this condition in children who are referred to us far more than we did. In these young children it is hard to get the finger into the nasopharynx without injury and examination with the mirror is out of the question. In such cases, if the child is held before a good light, the tongue depressed and the palate lifted up with a palate retractor, a very good view of the pharynx can be obtained. The question of anesthesia or non-anesthesia is more or less a question of the desire of the parents. Very little anesthesia is required, but as a rule I find that the parents prefer even that little. The Gottstein curette is a good instrument, but it has one disadvantage, namely, the possibility of cutting too deep. The Shütz adenotome, and the new one devised by Dr. LaForce, of Iowa, give good results.

With either of these instruments the entire adenoid can be removed with one stroke of the blade and practically as painlessly as the ordinary examination. A small adenoid curette devised by Vogel is then used in each fossa of Rosenmüller to be sure that no adenoid is left in this situation. The one essential thing in the young child, on account of the danger of getting an infection of the Eustachian tube, is to do the operation in a good light and see the field of operation; not merely to operate by the sense of touch.

Dr. Henry L. Coit, Newark: I have generally expressed myself as opposed to operation on adenoids in children under 1 year, but Dr. Freeman's plan is reasonable and convincing. My chief objections to the operation are the danger to small infants of anesthetics, and the fact that they do not well bear the loss of blood. I would be sorry to see this matter turned over to the throat and nose men if they go after these little children as they do after some others who do not have adenoids. I recall one case of a child of 14 months who had a continuous temperature, and the physician made a diagnosis of tuberculosis due to hypertrophy in the nasopharynx. An operation was done and they did not get anything. I was called, and after disproving tuberculosis, found that the child had never been weaned and was taking nothing but milk with still 7 per cent. sugar. There were malodorous stools, and besides this the child had indulgent parents and grandparents. I felt sure that faulty feeding was the cause of its malnutrition and fever. It was not a difficult feeding case, but a case of easy feeding with difficult parents and grandparents. A trained nurse was ordered for the purpose of hypnotizing the parents and weaning the baby and there was no further trouble.

Dr. John Lovett Morse, Boston: The members of the section probably remember that I read a paper on this subject two years ago. I want to exphasize again the fact that the symptomatology of adenoids in infancy is not that of adenoids in childhood. The symptoms in infancy are snuffles, repeated "colds," irritating cough at night, difficulty in nursing and otitis media. I believe that adenoids should be removed whenever they cause symptoms, no matter how young the baby is. I have seen them cause symptoms in babies only a few weeks old. I do not operate myself, because I believe that the operation demands the skill of a specialist. I disagree entirely with Dr. Coit and think that the operation should be performed by a man who is in the habit of doing these operations. I do not find that the specialists are unduly anxious to operate; in fact, my difficulty in Boston is to find men who are willing to operate on these babies for me. They object to operating on young patients and it is very difficult to make them appreciate how much harm adenoids may do in infancy. It is not recognized how frequently otitis media in babies is due to adenoids. A baby may have repeated attacks although the adenoids are very small. In fact, it is possible to overlook them in these cases unless a very careful examination is made.

Dr. Frank S. Churchill, Chicago: I do not think there is any danger of the throat and nose men operating too often. My experience also has been that they are afraid to operate on these babies. I have had difficulty in getting them to operate even when it is clearly shown that there are marked symptoms of adenoids. Unless there is something very urgent about adenoids or hypertrophied tonsils, I always like to have them operated on during the late spring or early summer, when the children will have time to recuperate before the winter. My experience has been that when operated on late in the fall the children are apt to have as many colds during the ensuing winter, or even more of them, than before the operation was done. It is hard to convince the nose and throat men of the fact because they do not see the children afterward. We do. That is a point on which I think the nose and throat men need education. As to a temperature of 100 of 101 F. being an indication for the removal of adenoids, I would want to be very sure as to what that temperature is due before having an operation done. I should want to watch the baby carefully for several days and make many cultures before subjecting it to an operation.

Dr. D. J. M. Miller, Atlantic City: I think that much of the odium that has fallen on this operation has been due to the fact that these patients have been so often subjected to an operation by some one not skilled in the work. I am much opposed to the general practitioner performing such an operation. When these symptoms occur in very young babies, it seems to me that the milder cases can be cured without operative interference by the continued use of a weak solution of iodin in glycerin, and by the use of antiseptic sprays. I have seen babies recover entirely under this treatment.

Dr. S. W. Kelley, Cleveland: As has been said, whatever the physician may wish, the question of anesthesia is often decided by the parents. If it is left to me I do not use an anesthetic when operating on infants. For this I have sometimes been criticized as cruel. In other cases the parents positively will not allow the use of an anesthetic. In operating without anesthesia a sitting posture is to be preferred. As to the manner of holding the patient, instead of having a sheet wrapped tightly about the chest and the nurse holding the patient over the arms with one hand and with the other hand holding the head of the patient, I prefer to have the nurse seated, reaching around from behind, hold the patient by the wrists, one in each hand, the patient's arms being crossed in front; and have an assistant, standing behind, hold the child's head between his hands, at the same time retaining the gag in place, unless a Whitehead gag is used. I object to scraping and crushing instruments, and prefer a sharp curette or one of the forms of guillotine.

Dr. W. D. Ludlum, Brooklyn: One point barely referred to is the question of recurrence. In my judgment these babies operated on very early, even when the operation is thoroughly done, sometimes have recurrences, and that I think is the reason of the indisposition on the part of specialists to operate even up to 2 years of age.

Dr. S. M. Hamill, Philadelphia: I am not ordinarily ultraconservative, and in a general sense I agree with what Dr. Freeman has said. If I understood him correctly, he does not operate in every case of adenoids, but only in those cases in which there is some evidence of obstruction or some definite interference with health. Of course, when there is some indication, I approve of the operation, but the idea of operating in every case of adenoid swelling, which may be but temporary, or on every child with otitis media merely because one thinks there may be some slight enlargement of the pharyngeal tonsil, as has been advocated, I believe to be wrong. I agree that the symptomatology of adenoids in early life differs from that in older children, but these symptoms are frequently only temporary and will disappear without operation, and unless the indications are very definite, I do not approve of operation during the first year. I believe also that, aside from the child, we have no right to subject the parents to the shock of any operation on an infant, which may be of questionable value.

Dr. R. G. Freeman, New York: As to temperature being a contraindication to operation, a persistent temperature of from 100 to 101 F., apparently due to the presence of the adenoid, is best eliminated by removing the adenoid. Recurrence of adenoids is due largely to the predisposition on the part of the child to produce adenoid tissue and not to defective operation, and it might well be questioned whether, if it were possible, it would be good policy to remove all adenoid tissue. It is, however, necessary to eliminate obstruction and irritation due to large adenoids.

Changes in the Hypophysis During Pregnancy.—Erdheim and Stumme have recently published an extensive monograph on this subject (G. Fischer, Jena), reporting research at Weichselbaum's Pathologic Institute at Vienna. The findings in 122 cases are classified. The hypophysis seems to increase in size and weight during pregnancies until it becomes permanently enlarged. The average weight in the multiparæ was 1.06 gm., with 0.81 gm. as the minimum, while the average for the primiparæ was 0.83 gm., with 0.65 gm. as the minimum. Some of the physical signs hitherto ascribed to the pregnancy are probably the result of this hypertrophy of the hypophysis, such as the swollen face, lips and hands sometimes observed toward the close of a pregnancy. A tendency to adenomatous hyperplasia was observed in fully 10 per cent. of the hypophyses examined.

SUPPURATIVE CONDITIONS IN THE JOINT REGIONS IN INFANTS AND YOUNG CHILDREN *

L. E. LA FÉTRA, M.D.
Associate in Diseases of Children, Columbia University; Assistant Attending Physician to the Babies Hospital
NEW YORK

Inflammations in and about the joints in children are interesting for several reasons. The anatomic diagnosis is very often puzzling. The point of invasion of the infecting germ is frequently impossible to discover; and, finally, the results of early treatment are surprisingly satisfactory, except in cases of general sepsis. In looking over the records of a large number of cases of inflammations in the region of the joints in patients under five years old, it is found that the cases fall naturally into certain groups to which it may be profitable to call attention. My topic does not include tuberculous arthritis, but it is important to keep in mind all the while the picture of tuberculous joint disease in order to mark the contrast to the conditions that will be mentioned. This is all the more necessary because the great body of physicians are prone to consider joint disease either as tuberculous, if chronic, or as rheumatic, if acute.

Rheumatism is so rare under two years that this diagnosis should be made in a young child only by exclusion of all other possible conditions. True, rheumatism does occur, both multiple and monarticular. When monarticular, and especially if involving the knee or hip, it makes one very anxious lest the condition be tuberculous. In fact, it is frequently mistaken for tuberculous joint disease. Inasmuch as rheumatism is so rarely a suppurative disease, I shall omit it from my discussion.

As those who see the conditions in their early stages, the members of this Section can do a great service in calling attention to other forms of joint involvement besides tuberculosis and rheumatism. With the acute suppurative conditions delay in treatment or treatment by fixation and rest, with or without traction, is apt to result disastrously.

SUSCEPTIBILITY TO JOINT INFECTIONS

The joints in infants and young children are very susceptible to all sorts of infections. The younger the child the more apt it is to have joint infection, and, moreover, the number of joints apt to be involved seems to be greater the younger the child. This susceptibility is undoubtedly due to the rapid growth taking place at the joint ends of the bones.

Any large joint may be involved but there is a proneness for the additional infection of the small joints of the wrist, hand and foot and sternoclavicular articulation.

Shortly after birth the infections most frequently met are those due to sepsis, and somewhat later, though still during the first few months, those due to the gonococcus. Both these infections are apt to be multiple. Between the first and fifth year the child may suffer from various types of infection of several or single joints. The infective agent may be the streptococcus, the staphylococcus, the pneumococcus, the typhoid bacillus, the influenza bacillus, and occasionally (with the hip joint) the colon bacillus. Children over five years old are much less apt to have suppurative conditions in the regions of the joints, and when they do occur the point of invasion can usually be determined. Joint disease in children over five is usually either tuberculous or rheumatic.

TYPES OF INFECTION

The groups of cases which it seems important to emphasize are the following:

I. Arthritis due to the streptococcus, or to the staphylococcus or to mixed infection by these germs.

II. Arthritis due to the gonococcus.

III. Arthritis due to the pneumococcus.

IV. Arthritis due to the bacillus of influenza.

V. Cases of osteomyelitis, including periostitis and epiphysitis.

VI. Cases of deep cellulitis.

VII. Cases of perinephritic abscess, psoas abscess and ischiorectal abscess.

I shall relate very briefly a few typical cases of some of the groups.

GROUP I.—ARTHRITIS DUE TO STREPTOCOCCUS OR STAPHYLOCOCCUS OR BOTH

Case 1.—*Purulent Arthritis of Shoulder Due to Streptococcus.*—T. R., 1½ years old, in Babies' Hospital from May 1 to May 20, 1903, had been a healthy baby; was nursed three days, then fed on condensed milk, rice water and soup; had chickenpox at 1 year. He had never walked; had no digestive disturbance; had purulent conjunctivitis at 9 months, lasting five weeks. He entered hospital with history of having had for three weeks a "sore shoulder." It was slightly swollen at first, growing steadily worse. The child was feverish at times. Physical examination showed the fontanel 1 inch in diameter and depressed. The child looked stupid. Heart and lungs were normal; abdomen flaccid; liver and spleen not enlarged; all superficial lymph nodes enlarged. The right shoulder joint was swollen and fluctuating but not red, though somewhat warm. Temperature was from 102 to 103. Aspiration drew thick, yellow pus, containing the streptococcus. Operation was done on May 4 under chloroform, incision being made into the joint. On the next day temperature was 102 F. at noon and the child was very restless. Being exposed to diphtheria he was given 500 units of antitoxin. On May 6 the temperature was under 100 and the wound was looking well. The child's weight on admission was 16 pounds, and on May 11, eight days later, was 17 pounds 4 ounces. On May 20 the weight was 17 pounds 8 ounces and the wound had entirely healed, joint motion being good.

Case 2.—*Multiple Septic Arthritis Due to Streptococcus, Bronchopneumonia, Acute Pleurisy.*—A. S., 20 months old, was in Babies' Hospital from Oct. 25 to Oct. 29, 1904. The baby was taken acutely ill with fever, but without vomiting or diarrhea, three days before admission to the hospital. She became very fretful, crying out when touched; had also slight cough. Examination showed numerous dry friction rubs but no change in the breathing sounds. Behind were heard fine crackling râles. There was some dulness on right base. Respirations were 80 to the minute. The spleen was two fingers' breadth below, liver one finger's breadth below ribs. There were some enlargements of the joints of both extremities. The left wrist was swollen and hot, the left ankle and foot also. There was a fluctuating swelling, painful, hot and discolored on the inner side of the right arm at about its middle. The temperature was 103 to 105.8 F.; pulse, 160; respirations, 60 to 80; leucocytes, 9,000. The swelling of the left wrist and the left dorsum of the foot persisted and the right shoulder also became red and swollen. On October 28 the leucocytes were only 7,000. On October 29 the temperature was lower and the baby died at 10 p. m. Examination for gonococci was negative. Aspiration of shoulder joint showed streptococcus pus. Autopsy showed the lesions mentioned above and also an acute nephritis.

Case 3.—*Mixed Staphylococcus and Streptococcus Arthritis of Knee.*—J. H., male, aged 20 months, was in the Babies' Hospital from Jan. 14 to Feb. 28, 1907. Four days previous to admission the child stopped walking and cried with pain in the feet. There was high fever and swelling in both legs below the knee. For two days the swelling was mostly in the left leg around the knee; great pain on motion. On admission the whole region of the left knee was red and swollen. Ice bags were applied. Temperature was 104. At operation on February 2 the knee joint was incised and 4 ounces of pus obtained. It showed staphylococci and streptococci. By February 28 the wounds were nearly well and motion of joint was good.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

CASE 4.—*Streptococcus Arthritis of Shoulder and Hip.*—J. S., male, 7 months old, was admitted to the Babies' Hospital Nov. 27, 1908. Three weeks before admission the child had abscess on the right side of the neck. There was some general rigidity after that time and six days before admission the child was said to have had a convulsion. At this time it was noticed that the left thigh was larger than the right and there was some pain on motion. On admission the left shoulder joint was found to be swollen and tender and the shoulder was not moved. The left hip was likewise larger than the right and the thigh held flexed by spasm. No definite point of fluctuation was made out. The following day Dr. Hartley aspirated the left hip joint, obtaining turbid yellow fluid which showed staphylococci and later streptococci. Three days later a retropharyngeal abscess containing streptococci was opened. One week after admission 37,500,000 dead streptococci were given by hypodermic injection. The temperature ranged from 99 to 102 and the joints remained swollen. Two weeks later thin pus was drawn from the left gluteal region and showed streptococci. The following day an incision was made into the left gluteal region and a small quantity of light yellow fluid obtained. The joint was not incised. No operative treatment was attempted for the shoulder, but both joints healed completely.

GROUP II.—GONOCOCCUS ARTHRITIS

During the past five years I have seen two cases of gonococcus arthritis at the Vanderbilt Clinic, both being monarticular, and there have been nine cases at the Babies' Hospital, most of which I have seen. Seven of these Babies' Hospital cases occurred in the gonococcus epidemic at the hospital in 1903 and 1904, and were reported in detail by Dr. Kimball. The remaining two cases occurred in 1907, and there was not a single case in the intervening years.

A peculiar feature of these cases is that they occur almost exclusively in male infants without any urethritis or other discoverable entrance port. One of my cases at the Vanderbilt Clinic followed gonococcus ophthalmia. The baby was three weeks old and had had ophthalmia from birth. The right knee became swollen and tender on the tenth day. By the use of alcohol dressing the inflammation was allayed and the synovitis subsided.

Another feature is that there are usually several joints involved and that the tissues around the joint as well as the joint itself are implicated. Often the para-articular swelling is the greater and on cutting through these tissues there is a large amount of serum and pus obtained, while there may be little obtained from the joints. There is fever for two or three days before the joint swelling appears, ranging from 101 to 103.

A final characteristic is that the inflammation, even though purulent, yields readily to treatment; usually to such simple measures as 60 per cent. alcohol compresses or aluminum acetate and alcohol, equal parts. If these measures are not successful, simple incision into the joint is all that is needed. The joints heal quickly with no impairment of the function.

Of course, some of the cases prove fatal.

The histories of two cases will be given briefly:

CASE 5.—*Multiple Gonococcus Arthritis.*—C. J., male, aged 2½ months, was in the Babies' Hospital from Jan. 25, 1907, to Feb. 18, 1907; died of bronchopneumonia. He was brought to the hospital on account of vomiting and cough. Twelve days after admission, i. e., on February 8, had temperature for two days up to 101 to 102.6. Then there appeared on the dorsum of the left foot above first metatarsophalangeal joint a tense swelling, with shiny skin. On the third day the temperature was 102 to 102.4, and the abscess was opened, ½ ounce of pus being evacuated from the joint. The next day temperature was 101 to 102.6 and the right ankle was swollen and tender but not fluctuating; the swelling seemed rather diffuse. By noon the second joint of the left forefinger was swollen and tense. Ice poultices were used. White blood cells were 13,100; temperature, 99 to 103.2. On the fifth day the metatarsal joint had closed. There was no fluctuating in the other three joints. The next day the ankle joint was much improved. On the eighth day the toe joint was again swollen and fluctuating so it was opened again, a small amount of thick yellow pus being obtained. This pus showed typical Gram-negative intracellular diplococci. Culture showed the same organisms. On the eleventh day the right sternoclavicular joint was swollen and the temperature went up to 104.8. The next day the baby developed a strip of bronchopneumonia and had a temperature up to 105, dying the following day.

CASE 6.—*Multiple Gonococcus Arthritis.*—E. v. E., 3 months old, male, was in Babies' Hospital from January 24 to March 16, 1907; admitted to hospital because he did not gain in weight and was vomiting. On February 11, just sixteen days after admission and two days after the case just mentioned developed, there appeared diffuse non-fluctuating swellings at the left ankle and at last joint of the right middle finger. The temperature had been elevated for two days from 100 to 103. White blood cells were 13,100. For the next four days no new joints were involved, but the temperature ranged between 99.8 and 102.6. On the fifth day the left elbow and wrist were swollen—a diffuse swelling seeming like a cellulitis or para-articular inflammation. On the seventh day aspiration but no pus. By the sixteenth day the temperature was about normal, and the joints remained swollen and tender. Sixty per cent. alcohol dressings were applied. On the twenty-fourth day diplococci were demonstrated in the thick green pus obtained from elbow and ankle; they were proved to be gonococci both by microscope and by culture. The patient was discharged with the joints still somewhat swollen, but not very tender.

GROUP III.—ARTHRITIS DUE TO PNEUMOCOCCUS

CASE 7.—*Arthritis of Shoulder (Probably Pneumococcus).*—H. F., male, 9 months old, was in the Babies' Hospital from March 14 to April 4, 1905; discharged cured. He had pneumonia in both lungs when 6 weeks old; was very sick for twelve days. For three months there was swelling of the shoulder joint. Just as the child was recovering from pneumonia the mother noticed that the shoulder was swollen, hot and red; it had been so ever since. There was irregular fever. The left shoulder joint was found to be swollen. The child did not move the arm, and, moreover, it could not be moved freely. There was slight fluctuation. The temperature ranged from 99 to 102.2. Aspiration of joint was made on March 21 and pus obtained, and the next day an incision was made into the joint and a large amount of pus was evacuated, most of which seemed to come from around the joint. By March 25 the temperature was normal and the leucocytes were 12,000. On April 4 the shoulder was healed.

CASE 8.—*Purulent Pneumococcus Arthritis of the Left Knee, Bronchopneumonia, Meningitis.*—A. McL., female, 8 months old, was in the Babies' Hospital from Nov. 21 to Dec. 10, 1903; discharged dead. The patient was apparently well until seven weeks before entering the hospital, when she had a typical bronchopneumonia on both sides. Recovery was satisfactory. A swelling of the left leg was present. When incised 2 ounces of pus which showed pneumococci was obtained. Following this there was considerable constipation. One week before entrance to the hospital there was vomiting of cerebral type. It was for meningeal symptoms that baby was admitted. The meningitis proved to be due to the pneumococcus as shown by examination of the cloudy fluid obtained by lumbar puncture. On admission the right knee was found enlarged and held flexed. The patella floated. Kernig's sign was absent on the right side; could not be tested for on the left because of rigidity of the knee. The symptoms while in hospital were those of acute meningitis.

GROUP IV.—ARTHRITIS DUE TO THE INFLUENZA BACILLUS

Case 9.—*Multiple Arthritis and Meningitis Due to Bacillus of Influenza.*—In the spring of 1907, in consultation with Dr. F. S. Fielder, I saw a 12-months old patient who had had cough, fever and prostration with comparatively high temperature and, in addition, swelling of the metacarpophalangeal joints of the right hand. Later the left wrist became swollen, and the right hip and one of the vertebral joints. The child was sick for twelve days and died with no definite symptoms of meningitis. We had agreed on the diagnosis of grip, but no lumbar puncture had been made and no withdrawal of joint fluid. But a very careful necropsy was made by Dr. Welch of the Cornell Laboratory, and from all these joints, five in number, was obtained a pure culture of the influenza bacillus, absolutely no other organism being present. At the necropsy examination of the brain was made, and from the sulci was obtained pus of similar character to that found in the joints. Moreover, the germs found by careful culture were also only those of influenza. This baby had had simply signs of great prostration; no signs of meningitis at all. It may be that the baby had meningitis from the beginning, but it was a most striking case of influenza bacillus septicemia with terminal meningitis.

GROUP V.—OSTEOMYELITIS, INCLUDING PERIOSTITIS AND EPIPHYSITIS

Case 10.—*Osteomyelitis of the Femur.*—M. A., 14 months old, was seen at Vanderbilt Clinic, Oct. 2, 1905; on October 2 was referred to Roosevelt Hospital. There was a history of some inflammation about the vulva six months previous, but there had been no vaginal discharge. For the previous week the left thigh had been swollen and recently had been increasing very rapidly in size. It was painful to the touch and was not used. There was no pain in the other leg nor in any other joints. The swelling of the left thigh was pear-shaped and involved the upper four-fifths. There was no fluctuation, but the thigh was very tender. There was general glandular enlargement. Temperature was 102.4. Operation evacuated pus which came from about the upper part of femur, not from joint.

Case 11.—*Probable Periostitis.*—B. B., aged 13 months, was in the Babies' Hospital from Nov. 18 to Dec. 18, 1907; had periostitis of the thigh following a perirectal and scrotal abscess. Three weeks before entrance the left thigh became swollen near hip joint; swelling increased toward the knee. There was marked pain on motion and child did not move the thigh. The swelling of the left thigh was very hard and not movable; seemed connected with the bone. The skin was tense but not red or shiny. Passive motion of the thigh at hip joint was possible. Temperature varied from 100.2 to 100.6. Ichthyol ointment was used on the thigh. After a few days temperature became normal and the swelling of the thigh subsided. When the child was discharged one month from the time of admission the thigh was much smaller and the baby's condition was greatly improved. In this case it is not positive that the inflammation was suppurative. It is probable that it was a periostitis.

Case 12.—*Probable Osteomyelitis of Epiphysis.*—J. F., male, aged 16 months, was in the Babies' Hospital from Aug. 13 to Aug. 20, 1906. Eight days after admission there was swelling on the lower part of the left leg. This swelling increased and prevented walking. Latterly there was redness and heat. The swelling was found to be over the lower end of the left fibula, most marked about the malleolus; but the redness extended below the ankle and to the back of the leg. There was fluctuation. The child would not bear his weight on the foot but passive motion at the ankle was possible. Two days after admission 1½ ounces of pus were evacuated through an incision made at the lower part of swelling. The connection with the bone was not made out. The child was discharged with the wound almost healed.

Case 13.—*Osteomyelitis of Epiphysis.*—E. W., male, 17 months old, was in the Babies' Hospital from March 23 to April 4, 1907. At noon on the day preceding admission the child seemed feverish, complained of pain in the right leg and refused to walk. The right knee was swollen on the morning of admission and the child kept the knee flexible. On examination the right knee and the tissues below it were found much swollen, measuring nearly two inches more than the opposite leg. The skin was shiny and there was some redness. Temperature was 103.4. Next day white blood cells were found to be 28,400, and of these 80 per cent. were polynuclear. Notwithstanding ice poultices and hot poultices, the swelling increased and became more tense. Two days later thick, green pus was evacuated through incision on right knee. The pus did not come from the joint but from below the joint. At the time it was not made out whether the bone was affected, but four days later denuded bone could be felt deep in the wound, showing that the point of infection had been the shaft of the tibia.

GROUP VI.—CELLULITIS

Case 14.—*Pneumococcus Abscess in Region of Knee.*—J. L., male, 7 months old, was admitted to the Babies' Hospital March 29, 1909. When 6 months old he began to have swelling about the right hip gradually extending toward the knee. He had always been well up to that time. About March 1 he was vaccinated and after that there was fever and the thigh became worse. Seven days before admission to the hospital the family physician aspirated fluid and then operated on the right thigh above the knee. On admission the patella was apparently floating, the knee swollen and held flexed. Pus was discharging from old wound above the knee. On the following day two openings were made into the abscess, one above and one below and to the inner side of the patella. The bone was not involved and the abscess seemed entirely superficial. Smear and blood from the wound showed pneumococci. Seven days after the first operation by Dr. Alfred S. Taylor the wound was reopened and an incision made into the external surface of the joint. A week later it was thought necessary to open the joint again, but an incision above the joint on the anterior aspect of the thigh obtained a large amount of pus. Culture from this showed pure staphylococci and no opening was found into the joint. The temperature after the operation ranged from 98 to 104, and so 50,000,000 dead streptococci were injected into the left arm on April 1. This was repeated on April 6, and on April 10 10 c.c. of Hiss's leucocyte extract was injected. On May 3 the left thigh was badly swollen and about 4 ounces of thick yellow pus were aspirated; 20 c.c. of normal horse serum were injected into the cavity. The culture from this pus showed short streptococci. From the time of the last operation the child improved very satisfactorily.

Case 15.—*Stereptococcus Abscess Around Left Hip Secondary to Infected Nevus on Face.*—E. H., female, 4 months old. When 3½ months old a small vein at the back of a nevus on the right cheek burst and there was a slight bloody discharge. After three days there were some small vesicles in this area which later discharged some pus. Next, the lymph nodes under the right jaw became swollen. The swelling was quite diffuse but subsided after a few days. At the same time it was noticed that the left leg was not moved but was kept flexed at the knee and the hip. The temperature ranged from 100.6 to 102 up to the day of my visit, when it ranged from 102 to 103.5. There was limitation of motion by muscular spasm and some enlargement of the left hip but no sure swelling of the joint. The baby was kept under observation, the thigh being immobilized in an aluminum acetate dressing. After two weeks the baby was operated on by Dr. William G. Erving of Washington, D. C. Aspiration of the abscess in the region of the left hip had shown a pure culture of streptococcus. The abscess when opened was found to be of considerable extent and had dissected out the trochanter and neck of the left femur, although the capsule of the joint seemed to be intact on exploration at that time. The abscess drained freely but did not heal until two months later. Meanwhile the baby's general condition gradually improved. The convalescence was uneventful save for suppuration of an infected lymph node below the right ear, which was the probable site of the original infection. One week after the healing of the wound in the thigh an *x*-ray examination showed apparent damage to the upper border of the acetabulum with slipping of the head upward out of the socket. Otherwise no bony damage was made out. From that time until the present, traction has been continued on the leg and passive movements are still carried on, so that while the capsule is still probably distended there is no measurable shortening. There is full rotation, full adduction, normal extension and 60 degrees of abduction; so that there is every reason to believe that the joint will be a good one. The baby's general condition is excellent. This report was received from Dr. Erving on May 29.

CASE 16.—*Deep Streptococcus Cellulitis Extending to the Bone.*—S. R., female, 14 months old, was in the Babies' Hospital January 15 to March 12, 1906; developed diphtheria and was discharged unimproved. She came into the hospital for pneumonia. Discharge from the nostrils showed influenza bacillus. Ten days after admission the patient developed swelling and redness of the right metatarsus. Temperature went up to 103 F. Three weeks after admission the patient developed swelling near the left knee joint, especially to the outer side of the patella. The patella did not float. Aspiration showed thick pus, pure streptococcus. On the following day this pus was evacuated by an incision to outer side of patella; the knee joint was not involved. Two weeks later there was swelling of the right shoulder in front, below and behind. Incision at angle of scapula evacuated several ounces of pus, which came not from shoulder joint but from around it. Cultures showed streptococci. At one place bare bone of the seventh rib could be felt. On account of the development of diphtheria the child was sent away; all the wounds were discharging; no joints involved.

CASE 17.—*Deep Cellulitis of Thigh Near Hip Joint.*—S. W., 5 weeks old, was in the Babies' Hospital from February 18 to March 14, 1906; discharged cured. The child had some gastro-intestinal disturbances from birth and stomatitis when ten days old. At 4 weeks a swelling was noticed in the left groin; this increased and became tender. It involved the inguinal glands and was at time of admission more marked on the outer side of the thigh. There was redness and fluctuation; the child did not move the leg; passive motion was painful. Temperature was 100.6. On the day after admission 4 ounces of thin pus were evacuated through an incision on the outer side of the thigh. There was pus in the tissues surrounding the bone but no communication with the joint. Cultures showed *Streptococcus b.eris.* The wound healed entirely in three weeks.

GROUP VII.—PERINEPHRITIC ABSCESS, ETC.

CASE 18.—*Perinephritic Abscess, Bronchopneumonia, Marasmus.*—H. D., 7 months old, was in the Babies' Hospital from Jan. 21 to Feb. 22, 1904. Death occurred from bronchopneumonia. The baby was brought to the hospital because it was wasting and crying all the time and had fever. On examination the abdomen was found enlarged, its superficial veins distended over the diaphragm. The liver was one inch below the ribs and the spleen just felt. Superficial lymph nodes were found slightly enlarged, particularly near the axillæ. The abdomen became more distended while in the hospital and began to point in back on the left side. Temperature ranged from 102 to 103.8. On January 30 the abscess was incised and about 1 ounce of pus removed. After the operation the temperature varied according to the freedom of the discharge. Finally the baby refused food and died in an attack of edema of the lungs.

DIAGNOSIS

In general the first point in diagnosis is to determine whether or not the inflammation involves the joint. This would rule out scurvy and syphilitic epiphysitis. It is difficult to say at the outset that the joint is not involved; even after operation the surgeon may at times be in doubt. Next the diagnosis should be made from tuberculosis and rheumatism. Deep cellulitis of the thigh, perinephritic abscess and ischiorectal abscess should be carefully distinguished from disease in the hip joint.

TREATMENT

It is remarkable that wet dressings of aluminum acetate or of 60 per cent. alcohol or of these lotions combined succeed in a surprising number of cases. If progress is not satisfactory, incision should be made at an early date. The operation need be simply an incision into the joint with evacuation and provision for thorough drainage. It is remarkable that such simple measures succeed so frequently not only in saving life, but in securing perfect functional results. Of course, when the bone is diseased, the infected focus should be thoroughly scraped out. Vaccine therapy, especially the use of streptococcus and staphylococcus vaccine, is often a very valuable aid.

CONCLUSIONS

1. Cases of arthritis and of what might be called "near-arthritis" are quite common in infants and young children.

2. In all cases a careful history of the infant from birth should be obtained. The inquiry should be directed particularly toward obtaining a history of umbilical infection, of early ophthalmia, of vaginitis, of pneumonia, typhoid and influenza.

3. The feeding history, especially the use of sterilized, carbohydrate, or proprietary foods, should be carefully scrutinized. An inspection of the gums may save an incision into the thigh. It goes without saying that the patient should be undressed entirely for examination. Men frequently fail in diagnosis, not because they do not know, but because they do not see the patient and do not make use of what they know.

4. The diagnosis of tuberculosis and rheumatism should be made by exclusion.

5. The earlier proper treatment is instituted the fewer the number of joints involved and the greater the chance of complete recovery of function.

110 East Sixty-second Street.

ABSTRACT OF DISCUSSION

DR. C. N. DOWD, New York: The symptoms of these joint infections and other infections in infants are often so similar that diagnosis is very difficult and the most skilful and astute practitioner may fall into the trap thus constructed. Two illustrative cases have recently come to my notice—in one a meta-pneumonic hip inflammation was believed to be due to intestinal disorder. The physician and the diet were changed and hard feeling was engendered which could not even be allayed after the hip abscess was opened and the baby had recovered. The second case presented a particularly unfortunate sequence of events. A child of 1½ years, previously well, awakened from his nap crying, and from that time was feverish and ill. The attending physician, unable to relieve him, called in a well-known pediatrist, who believed the trouble to be intestinal and advised accordingly. A little later another pediatrist was called and then an orthopedic surgeon and after a few more days a general surgeon. An *x*-ray picture was then taken, as the region of the right hip was evidently the place of maximum inflammation. This picture revealed no abnormality, but a large abscess was opened a few days later just above Poupart's ligament. Prompt healing followed and all seemed well for a time. A few months later, however, a limp was noticed and examination and another radiogram showed a really serious condition—an absence of the head and neck of the femur, which had been destroyed by the inflammation. This, of course, made a permanent and very disturbing deformity. These cases are cited to illustrate the difficulties of diagnosis and the possible seriousness of the disease and also to indicate our debt to Dr. La Fetra for calling our attention to so important a subject.

Value of Playgrounds.—The head of the schools of New York city says: "Public playgrounds have induced children to come to school whom we could not previously reach; they are a potent instrumentality for raising the health, mentality and morals of the community."—*Hygiene and Physical Education.*

PRIMARY HEMORRHAGIC GLAUCOMA, WITH PROBABLE SYMPATHETIC INFLAMMATION

A CLINICAL AND MICROSCOPIC STUDY OF A CASE *

MORTIMER FRANK, B.S., M.D.
CHICAGO

Pathologic investigations on hemorrhagic glaucoma have been reported in considerable number, but, owing to the peculiar combination of conditions, this case is of interest and we can, I think, make some useful deductions from it. It points out that a broad iridectomy freeing the filtration angle is not always a preventive of glaucoma, although iridectomy is the best method of treating acute glaucoma. It further indicates that diminished depth of the anterior chamber and narrowing or closure of the filtration angle are not absolutely essential for the production of glaucomatous symptoms, but that, perhaps, hypersecretion and changes in the character of the fluids of the eye impeding proper filtration are sometimes concerned in the onset of glaucoma.

History.—On the evening of Jan. 14, 1908, I was called to see M. R., a man aged 31, of Jewish extraction. The day before the patient went to Milwaukee on a business trip feeling as well as usual, never having had any severe illnesses or any previous eye trouble. Twenty-four hours prior to coming under observation he suffered with a sudden severe pain in the left eye and within two hours the globe was intensely injected and vision lowered so that he could barely make out his hand. After a long anxious night a well-known Milwaukee ophthalmologist was consulted in the morning, who told the patient to get back to Chicago as quickly as possible.

Examination.—The left eye presented all the cardinal symptoms of acute glaucoma. The globe was brick-red, the scleral vessels full and the cornea steamy with diminished sensibility. The anterior chamber was equal in depth to its fellow and contained about two minims of dark-colored blood. The pupil was fully dilated and immobile, with the characteristic glaucoma reflex. The tension was plus 3. An ophthalmoscopic examination was impossible, owing to the corneal haziness and cloudiness of the vitreous. The vision was reduced to counting fingers at two feet. To the temporal side of the globe there was a large subconjunctival hemorrhage extending to the limbus and at places in the vicinity the cornea appeared to be studded with minute hemorrhages. The field of vision was about normal. The pain in and about the eye was very severe. The fellow eye was absolutely quiet and normal in every detail; vision equaled 6/6 plus. A careful inquiry into the patient's previous history failed to ascertain any cause for the attack. His habits were the best; he drank and smoked only very moderately. There was no venereal history. It was evident that one had to deal with a case of primary glaucoma of the hemorrhagic type. As iridectomy was not advisable, the usual medical remedies, eserin (physostigmin), one grain to the ounce, combined with cocain, dionin (ethyl-morphin hydrochlorid) 5 per cent., leeches and hot fomentations had to be relied on.

January 15, 8:30 a. m.: The patient had a good night and was now free from pain; T + 3; cornea hazy; anterior chamber of normal depth; pupil widely dilated, but hyphema less marked.

January 15, 8:30 p. m.: Condition was the same, except that the blood in the anterior chamber has absorbed, and cornea clearing and sensitive. T + 3; vision equaled fingers at six feet. On careful repeated chemical analysis and microscopic examination the urine proved normal.

January 16, 8:30 a. m.: The pupil was still dilated, but tension slightly lower than the day before. Cornea was bright and vision equaled 3/60. Ophthalmoscopy was now attempted, but owing to the cloudiness of the vitreous, the details of the fundus were not sharply defined, although the disc could be seen and appeared hyperemic, swollen and the vessels full. The retina could not be studied.

January 16, 8:30 p. m.: Since noon the patient had had some pain; the cornea was again steamy and vision reduced to fingers at two feet. The field was good. Paracentesis of the cornea was advised and concurred in by Drs. Casey Wood and Thomas Faith. On account of the previous hyphema and the still present subconjunctival hemorrhage, iridectomy was advised against.

January 17, 8:30 a. m.: The patient's condition was the same. Under 10 per cent. cocain anesthesia, the anterior chamber was slowly emptied with a paracentesis needle, and immediately on the escape of the aqueous small rivulets of blood made their appearance on the iris. Tension was slightly lower than normal, and iris somewhat contracted. Physostigmin was instilled in both eyes and the eye which had been operated on was bandaged.

January 18, 8:30 a. m.: The bandage was removed. Anterior chamber reformed; cornea clear; pupil dilated ad maximum. T + 3, and vision equaled fingers at one foot. Hemorrhages were absorbed. A posterior sclerotomy was now made between the superior and external recti muscles under 10 per cent. cocain, and about 10 minims of a clear, straw-colored fluid escaped. The eye was very soft. Calcium chlorid in fifteen-grain doses was given every three hours, with a view of increasing the coagulability of the blood. In addition, nitroglycerin was given, 1/100 grain, four times a day.

January 19, 8:30 a. m.: T + 3. The eye was free from pain; the pupil fully dilated; the field good. The vision equaled fingers at one foot. Small hyphema present and the cornea was slightly hazy.

January 19, 2:30 p. m.: Hemorrhage disappeared. Dr. W. H. Wilder in consultation agreed with me in still holding out against an iridectomy. A combined paracentesis and posterior sclerotomy between the inferior and external recti muscles was made, under 10 per cent. cocain. Directly after the sclerotomy, bright red blood flowed into the lower part of the anterior chamber, appearing to come from the region of the iris root. The eye was very soft.

January 20, 8:30 a. m.: The bandage was removed. The cornea was clear; hemorrhage absorbed; pupil widely dilated; no pain.

January 21, 9 a. m.: The patient's condition was unchanged. The use of physostigmin, 3 grains to the ounce, was begun.

January 21, 2 p. m.: T + 3. The pupil was slightly contracted; now about 4 mm. in diameter; was still free from pain excepting after instillation of physostigmin. Blood pressure and coagulation time were taken by Dr. Adolph Gehrmann of the Columbus Laboratories, who found blood pressure 95 mm., pulse 80, coagulation time two to three minutes. The blood pressure was taken every day following for a week, and never went higher than 115 mm.

January 22, 8:30 a. m.: Condition was as noted yesterday afternoon.

January 23: The pupil about the same; tension slightly lower. Physostigmin was increased to 4 grains to the ounce.

January 24: Pupil was 4 mm., but there was a perceptible diminution in tension; cornea clearing.

January 25: The condition was unchanged.

January 26: The cornea was bright. The patient counted fingers at three feet: there was no change in tension from that last noted. Owing to the cloudiness of the vitreous, a view of the fundus could not be obtained.

January 29: The pupil was 2 mm.; tension + 1.

January 30: The tension was normal; field was taken (Fig. 1) and the eye transilluminated for a possible tumor, but found negative. The patient counted fingers at one foot.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

February 4: The eye was nearly white; the tension normal; vision, 6/60; the pupil 3 mm. in diameter. This condition remained until February 11, 1908.

February 12, 8:30 a. m.: At about 4:30 p. m., February 11, there was some pain in the eye, which continued during the night, but the patient attributed it to the use of physostigmin. Examination now showed a new atack. The cornea was steamy; tension + 2; pupil about 4 mm. in diameter; the anterior chamber of same depth as its fellow. Iridectomy was now advised as a last resort, and the patient made aware of the possible danger. Operation was done under 10 per cent. cocain anesthesia, and a broad iridectomy performed with a Landolt keratome without a mishap.

February 13, 2 p. m.: The patient had been very comfortable; was free from pain. The bandage was removed; the cornea was clear: the anterior chamber reformed. Tension was slightly subnormal. The pupil was 4 mm.

February 16: Tension was normal; the eye quiet; physostigmin was reduced to 1 grain to the ounce.

February 17: The condition was the same. With the ophthalmoscope numerous large clots were seen floating in the vitreous, but nothing further could be distinguished; the patient was given syrup of hydriodic acid.

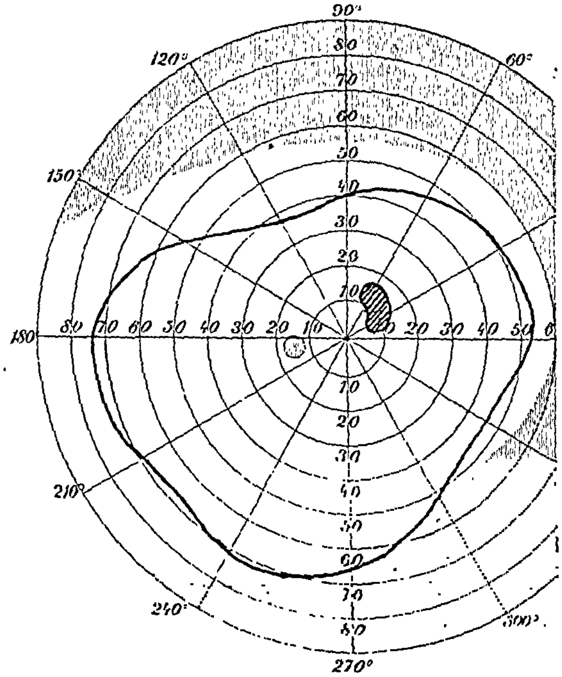

Fig. 1.—Field of vision for white (left eye), taken Jan. 30, 1908. Bright morning. Pupil 3 mm. in diameter. Disc, 1 cm.

February 27: The condition was the same. The vitreous had cleared so that the location of the disc with vessels could be made out. The vision equaled 6/60.

March 1: I did not see the patient from February 27 until this day. Tension was normal, but there was a broken ring of pigment on the anterior capsule, and one corner of the nasal pillar of the coloboma adherent to capsule. Physostigmin was stopped.

March 11: There was no change in the eye until this day, when a dust-like exudate was found on Descemet's membrane. Tension was slightly above normal; cornea clear.

March 12: The patient had pain during the night. The cornea was steamy; tension + 2. The use of pilocarpin was begun.

March 13: Tension was normal. The cornea was clear; keratitis punctata well marked.

March 14: Up to this date the right eye had been absolutely free from any discomfort, but this day there was a fine ciliary injection, some lachrymation, and a feeling of discomfort. Tension was normal. On examination with a loupe, numerous fine dots were seen on Descemet's membrane, which stained deeply with fluorescin. Right eye vision equaled 6/5 minus. Accommodation was impaired. The disc was slightly hyperemic and the vitreous hazy. The left eye tension was normal. The vision equaled fingers at four feet. With these conditions, enucleation of the left eye was immediately advised and done under ether anesthesia.

March 14: Treatment was given, consisting of mercurial inunctions, pilocarpin sweats, sodium salicylate, dionin 5 per cent. in right eye.

March 28: Exudate was absorbing on Descemet's membrane; there were large masses of exudate in vitreous. The disc was slightly hyperemic. Tension was normal. Vision equaled 6/7. There was a large subconjunctival hemorrhage in stump of enucleated eye.

April 18, 1908: Right eye vision was 6/6 plus; a few very fine spots of exudate were still visible on Descemet's membrane, with the loupe. The vitreous opacities were smaller; eye accepted + 0.75 D sphere; vision equaled 6/6.

February 23, 1909: The external eye was normal; the vision equaled 6/5 —. Some vitreous opacities were still present and a few very fine dust-like opacities were still remaining on Descemet's membrane.

MICROSCOPIC REPORT

The eye was given to Dr. E. V. L. Brown for anatomic study, and he has submitted the following report:

"The specimen (Lab. No. 264) was fixed in formalin followed by Zenker's fluid, and was cut in an anterior and posterior half, the anterior half sectioned throughout the area of the coloboma and the posterior sectioned horizontally. Some 400 serial sections of each half were made and every fifth or tenth stained.

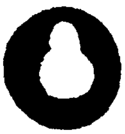

Fig. 2.—Anterior half of left eye as seen from behind (exact size).

"Seen from behind, the anterior half presented the appearance sketched in Figure 2; the lens is clear, the pars plicata and corona ciliaris are *in situ*, the processes and plicæ apparently normal and regular in arrangement. An accurate sketch of the position and extent of the operative coloboma area was made, because, clinically, a perfect and entirely effective iridectomy had been performed. No portion of the root of the iris could be seen behind the opaque corneoscleral limbus, either before or after the eye was taken out; yet, as shown in the sketch, the gross specimen shows that a good 0.5 mm. of the root of the iris had not been removed by the operation.

"*Microscopical Study.*—In a section through the center (section 205; see photomicrograph, Fig. 3) the curvature of the cornea and sclera are seen to be about the same. The cornea shows a tendency to collapse, and the center is slightly thinned to 0.5 mm. The epithelial layer is narrowed and elevated into empty vesicles in a number of sections; some of these (as section 110) have ruptured and left Bowman's membrane exposed. The outer cells are compressed and keratosed; the inner cell nuclei are thrown slightly forward or 'stilted'; many leucocytes are seen among the cells, esepcially in the upper portion of the cornea. Bowman's membrane is everywhere a trifle wider than normal and shows numerous delicate nerve canals as cross-striations. The body of the cornea is normal, although the very center takes a lighter eosin stain than usual. A narrow densely nucleated scar, corresponding to the site of the corneal section for the iridectomy, lies at the upper limbus: it commences just above the end of Bowman's membrane and runs obliquely from without, inward and downward at an angle of 45 degrees from the end of Bowman's membrane to a point 2.3 mm. central to the upper end of Descemet's membrane. Here at its inner end the cut layers of the cornea gape slightly, so that the anterior chamber bays forward into the back part of the cornea. The defect has the form of a narrow wedge, and both lips are bordered by the curled-up ends of Descemet's membrane; the surface of the triangle is covered by a single layer of new endothelial cells directly continuous with those lining the anterior chamber. The anterior end of the scar grades off into a mass of proliferating endothelial and stroma cells just beneath the limbus epithelium. A closely knit matrix of new stroma cells has definitely healed together the anterior three-fourths of the wound. In more temporal sections (see section 185) the defect produced by the operation extends forward as a narrow sinus one-half the way to the surface of the cornea. But the lips of the wound anterior to the sinus are so firmly knit together that no 'filtration cicatrix' could have been present. In sections still more temporal (such as section 110) several well-filled vessels of small size are seen running through the scar and are surrounded by considerable numbers of round cells. In all sections through the scar the surface epithelium is normally reformed, but nowhere dips down into the wound tract; the final repair has been effected entirely by proliferation of the fixed corneal cells. The lower one-half of Descemet's endothelium is thinned and the cells in part disintegrated; many clumps of small round cells and pigment detritus are found on the posterior surface of the cornea; some sections (Cf. section 110) showing as many as six clumps in the lower angle of the anterior chamber.

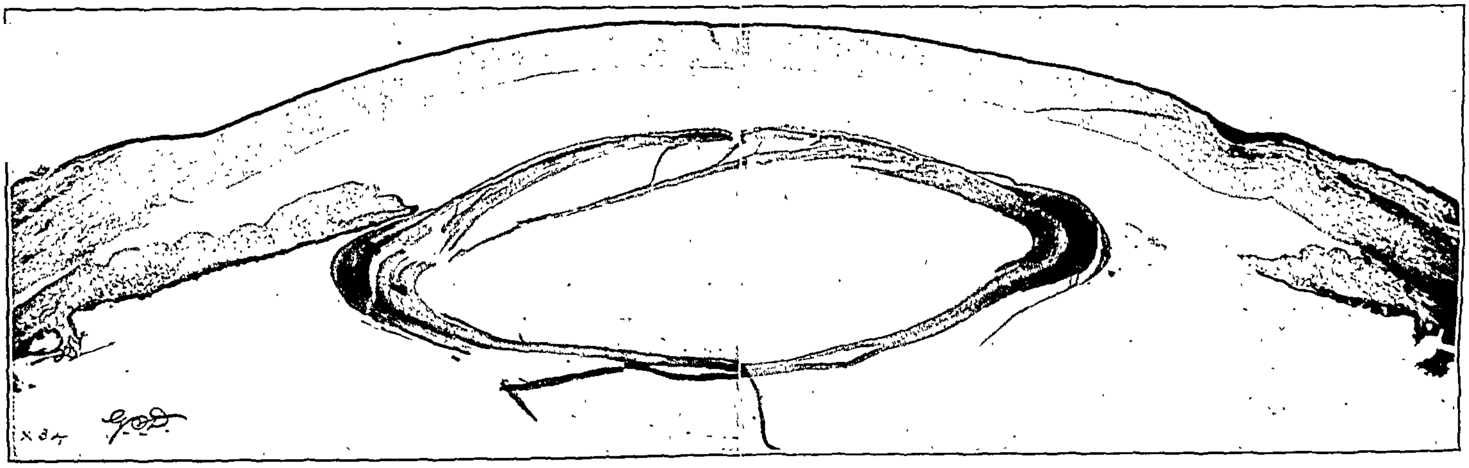

Fig. 3.—Section of left eye (photomicrograph, magnified 17 times). The upper limbus with the corneal incision and iridectomized iris lie to the right. One notes that: (1) The cornea is thinned; (2) the lens is thrown forward; (3) the chamber is shallow; (4) the sinus angles are open; (5) the trabeculum corneosclerale in infiltered on each side; (6) the canals of Schlemm are open; (7) pigment epithelium is detached from the iris pupil zone and adherent to the lens capsule; (8) the iris stump above is 1 mm. long.

"The conformation of the anterior chamber and the sinus angles deserve special description. The entire lens system and iris body have been displaced forward, narrowing the chamber as a whole; indeed, the anterior pole of the lens rounds forward through the pupil to such an extent that the space between the anterior capsule and the cornea is reduced to two-thirds of a millimeter. The plane of the iris below is correspondingly thrown forward, and makes an angle of 25 degrees with the transverse axis of the eye in comparison with a normal angle of about 15 degrees. Yet the sinus angles are patent in all sections both above and below, and the fluids of the chamber have free access to the surface of the trabeculum corneosclerale; the angle above is reduced to a narrow slit but is free from cells. The iris below measures 3.23 mm. from the pupillary margin to the circulus major, whereas the iris above has been in a large part cut away by the iridectomy; the iridectomy extends from section 49 temporal to section 213 nasal; the columns are nearly parallel and nowhere in contact with the wound. The stump lies entirely behind and peripheric to the corneal portion of the corneoscleral limbus, corroborating the statement made above that the iridectomy clinically was a very peripheric one: yet accurate measurement of the shortest portions of the stump shows that over 1 mm. of iris, measured from the circulus major to the cut end, is still present (section 143). As stated before, the angle does not show any accumulation of round cells or plastic material in any section; a heavy eosin stain does not bring out more fibrin or albuminous material than would be expected in aqueous reformed after evacuation. What fibrin is present is almost entirely in the lower half of the chamber and disposed along its walls.

"The sinus angle above is wider than that below; the cut end of the iris stump does not reach the equator of the lens anywhere and consequently the iris above has been displaced backward into a position that is even more nearly at right angles to the optic axis than in a normal eye. The iris below is thrown forward so as all but to touch the base of the cornea in many sections; indeed, some anterior root synechia to the back portion of the trabeculum corneosclerale has taken place in the sections which go through the angles just a little temporal to the iridectomy area; sections still more temporal are again perfectly free from any evidence of union between the periphery of the iris and the back part of the trabeculum corneosclerale. Both surfaces are perfectly smooth and sharply defined in all except a few peripheric sections (as, for instance, section 49) which show good-sized pigment masses.

"The anterior half of the iris, trabeculum corneosclerale and canals of Schlemm are infiltrated with round cells; those in the iris are almost exclusively of the plasma cell type and only moderate in amount; the posterior layers of the iris do not show any considerable amount of cell increase; the stroma pigment cells are considerably disturbed toward the iris root both above and below. In most sections the infiltration about the canals of Schlemm is so dense or the cells so changed that only round heavy-staining nuclei are seen and the type of cell can not be made out. Despite this, the lumina of the canals are free and lined by a well-preserved endothelium in most sections and filled with blood in many; the position of the canals can always be readily made out. Further evidence of plastic inflammation of the iris is furnished by deposits of pigment detritus, clumps and short strips of pigmented cells on the anterior surface of the lens capsule. Their exact location and the relations to the pupil border of the iris are of great importance in any attempt to establish an order of pathogenesis in the findings.

"In the sections which go through the temporal (sections 60-120) or nasal (sections 144-205) portion of the lens capsule the pigmented cells lie in about the center of the portion of the capsule shown and these (vertical) sections go through two areas, each about 5 mm. wide, in the horizontal plane. The central sections (120-144) show no deposits on the center of the part of the lens capsule concerned, but do show deposits more toward the equator of the lens; these central sections go through a pupil area of about two-thirds of a millimeter in diameter. These evidences of posterior synechia, therefore, extend through an area 5 mm. in width and are absent through a zone of two-thirds of a millimeter corresponding to the size of a normal pupil. Furthermore, there was no actual posterior synechia present at the time the eye was removed, because no sections show adhesion betwen the iris and lens; the slight expanse of the iris below (only 3⅓ mm. overlap the lower equator of the lens for a millimeter in section 133) means that the pupil was well dilated at the last. One may conclude, therefore, that there was first formed a central posterior synechia in a zone corresponding to the position of the sphincter at a time when the pupil was small, and that this was later broken up by dilatation of the pupil and did not reform. These facts are in keeping with the clinical history.

"The ciliary body is markedly atrophic; the processes are all directed forward and much flattened down against the muscular portion of the body. The muscle has lost its triangular form and instead of a prominent angle on the inner anterior face, it presents a very flat curve extending forward from the region of the equator of the lens forward to the canal of Schlemm. No cell increase is found in any part of the ciliary body, and the stroma does not show any increase of connective tissue; a few of the processes are matted together at their bases; the apices are all free and there are no cells, fibrin or new tissue in the zonula ciliaris or anterior vitreous.

"The chorioidea is *in situ* and absolutely without any evidence of active or past inflammation, except where one of the sclerotomies was performed. Here the scleral wound is well healed externally, though gaping slightly internally; the cut ends of the chorioidea and retina are closely in apposition or slightly prolapsed in to the inner angle of the wound; the chorioidea shows round-cell infiltration for one-half to three-fourths of a millimeter only on each side of and in the wound and in a few sections only (section 289 and section 320); here the sclera is slightly ectatic. The chorioidea is not at all thickened by the process; the infiltration is never more than eight or ten cells in width from within outward; no epithelioid cells can be found; and the whole process apparently represents only normal wound healing after posterior sclerotomy. The retina in this area is atrophic and fused with the chorioidea into a dense atrophic scar permeated by broken-down pigment epithelium. Several *Drusen* bodies are found in the anterior part of one section, 380.

"Elsewhere the retina was detached in preparation and shows no evidence of inflammation aside from mantles of round cells about some vessels; it is markedly thinned. The vitreous is slightly shrunken in bulk, but otherwise quite normal aside from a considerable amount of fresh blood near the ora serrata below.

"One hundred and ninety serial sections through the portion of the optic nerve immediately behind the disc and including the entire course of the central vessels within the nerve show no evidence of inflammatory or atrophic changes in the nerve substance, and no changes in the blood vessels.

ANATOMIC SUMMARY

"We have therefore an active chronic iridocyclitis, healed operative corneal and scleral wounds, and an operative coloboma of the iris above. The eye shows effects of increased intraocular pressure in the displacement of the iris and lens system forward, in the flattening of the ciliary body and in the marked atrophy of the retina. No anatomic-or histologic evidence of sympathetic inflammation is present. The presence of the chronic iridocyclitis throws doubt on the clinical diagnosis of primary glaucoma, and it is impossible to say from the anatomic findings that an anterior uveitis without clinical signs had not preceded and caused the glaucoma."

The conclusions deduced from the microscopic examination deserve careful consideration on account of their differences from the clinical findings. First, as to the non-existence of anatomic or histologic evidence of sympathetic inflammation: Although the changes in the iris, ciliary body and chorioid, as described by Fuchs, were absent, nevertheless the clinical symptoms were those of a sympathetic inflammation. Whether this was due to some agent entering the exciting eye as the result of the iridectomy, paracentesis or sclerotomy, I am unprepared to say. Until the pathologic anatomy of infiltrative-proliferative uveitis as described by Fuchs is found in all cases, and more firmly established as a pathognomonic finding, our diagnosis must be based on the clinical manifestations of the disease. The mere fact that the anatomic findings in this eye show a chronic iridocyclitis does not prove that it preceded the glaucoma and made it a secondary glaucoma, since the clinical precipitates on the posterior layer of the cornea and posterior synechia were not present until eight weeks after the onset of the primary glaucoma; but they did follow just exactly twenty-eight days after the iridectomy, and may very well have caused it. The patency of the sinus angles in all sections, and the lumina of the canals of Schlemm, free and lined by a well-preserved endothelium in nearly all sections, is striking and deserves careful consideration. That a gross obstruction of the filtration angle at any point in the filtration zone accounted for the increased intraocular pressure is not at all probable, and the fact that another attack followed iridectomy seems to be both pertinent and conclusive. It is more reasonable to assume, according to Priestley Smith, Bulson and Troncoso, inasmuch as primary glaucoma in a certain group of cases is dependent on disease of the blood or blood vessels causing an excess of fluid in the vitreous chamber, the exit of which is prevented by the swollen ciliary processes, or on alteration in the constitution of the intraocular fluids with failure in drainage, that the acute glaucoma here was dependent primarily on some vascular disturbance. As a result of this vascular disturbance, possibly due to some form of toxemia, there is diminution in the circulation of the blood favoring the occurrence of hemorrhages which result rather from transudation than from ruptured vessel walls.

ABSTRACT OF DISCUSSION

Dr. S. D. Risley, Philadelphia: I have no adverse criticism to express concerning the treatment pursued, but I think that there is opportunity for another opinion than that given in the paper, as to the nature of the case. This man was free from arteriosclerosis. He was a healthy man, 31 years of age. The attack came on suddenly, without clinically recognized cause, and throughout the subsequent history of the case the different manifestations are, to me, unique. It is only when we come to the laboratory study of the enucleated eye that we get any light on its essential nature. The hemorrhages, which occurred, it should be borne in mind, only after the increase in tension came on, throw some light on the case. Whether the intraocular hemorrhage shall occur, as has been suggested here, during the period of low tension, or whether it shall occur with very high tension depends altogether on which set of vessels furnish the hemorrhage—the arteries or the veins. If we let up the tension very suddenly in a glaucomatous eye with high tension, by iridectomy or otherwise, it is natural that we should expect hemorrhage from a rupture of the retinal arteries or arterioles, whereas the higher the tension the greater the engorgement of the venous system of the eye becomes and therefore venous hemorrhage is more and more imminent. This man had no arterial disease, but the pathologic study of the ball shows that there was unquesend the cut layers of the cornea gape slightly, so that the anterior chamber bays forward into the back part of the cornea. The defect has the form of a narrow wedge, and both lips are bordered by the curled-up ends of Descemet's membrane; the surface of the triangle is covered by a single layer of new endothelial cells directly continuous with those lining the anterior chamber. The anterior end of the scar grades off into a mass of proliferating endothelial and stroma cells just beneath the limbus epithelium. A closely knit matrix of new stroma cells has definitely healed together the anterior three-fourths of the wound. In more temporal sections (see section 185) the defect produced by the operation extends forward as a narrow sinus one-half the way to the surface of the cornea. But the lips of the wound anterior to the sinus are so firmly knit together that no 'filtration cicatrix' could have been present. In sections still more temporal (such as section 110) several well-filled vessels of small size are seen running through the scar and are surrounded by considerable numbers of round cells. In all sections through the scar the surface epithelium is normally reformed, but nowhere dips down into the wound tract; the final repair has been effected entirely by proliferation of the fixed corneal cells. The lower one-half of Descemet's endothelium is thinned and the cells in part disintegrated; many clumps of small round cells and pigment detritus are found on the posterior surface of the cornea; some sections (Cf. section 110) showing as many as six clumps in the lower angle of the anterior chamber.

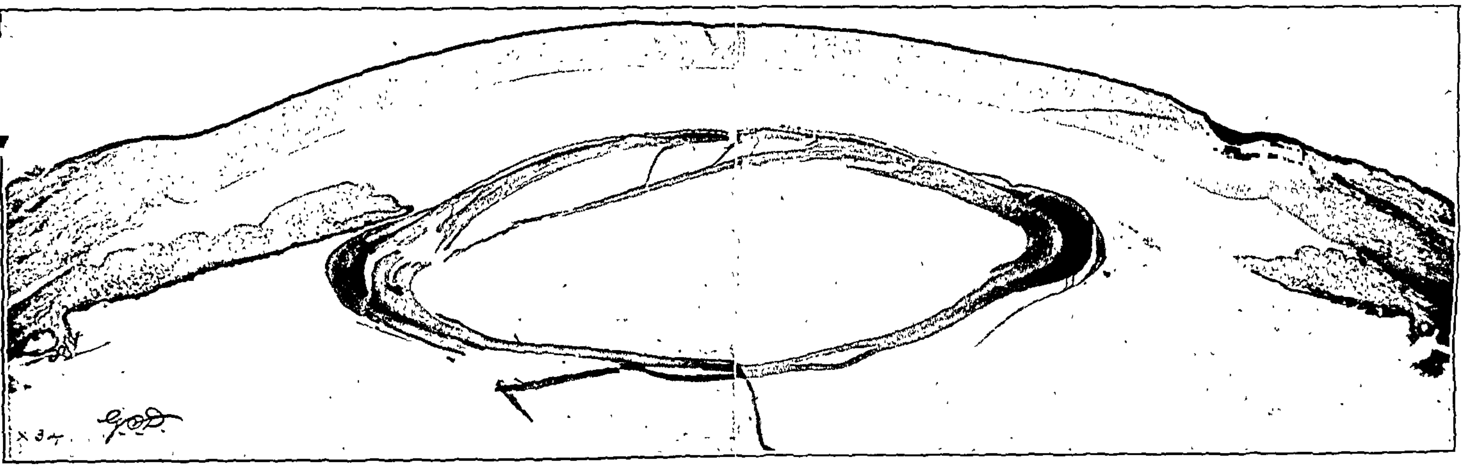

Fig. 3.—Section of left eye (photomicrograph, magnified 17 times). The upper limbus with the corneal incision and iridectomized iris lie to the right. One notes that: (1) The cornea is thinned; (2) the lens is thrown forward; (3) the chamber is shallow; (4) the sinus angles are open; (5) the trabeculum corneosclerale in infiltered on each side; (6) the canals of Schlemm are open; (7) pigment epithelium is detached from the iris pupil zone and adherent to the lens capsule; (8) the iris stump above is 1 mm. long.

"The conformation of the anterior chamber and the sinus angles deserve special description. The entire lens system and iris body have been displaced forward, narrowing the chamber as a whole; indeed, the anterior pole of the lens rounds forward through the pupil to such an extent that the space between the anterior capsule and the cornea is reduced to two-thirds of a millimeter. The plane of the iris below is correspondingly thrown forward, and makes an angle of 25 degrees with the transverse axis of the eye in comparison with a normal angle of about 15 degrees. Yet the sinus angles are patent in all sections both above and below, and the fluids of the chamber have free access to the surface of the trabeculum corneosclerale; the angle above is reduced to a narrow slit but is free from cells. The iris below measures 3.23 mm. from the pupillary margin to the circulus major, whereas the iris above has been in a large part cut away by the iridectomy; the iridectomy extends from section 49 temporal to section 213 nasal; the columns are nearly parallel and nowhere in contact with the wound. The stump lies entirely behind and peripheric to the corneal portion of the corneoscleral limbus, corroborating the statement made above that the iridectomy clinically was a very peripheric one: yet accurate measurement of the shortest portions of the stump shows that over 1 mm. of iris, measured from the circulus major to the cut end, is still present (section 143). As stated before, the angle does not show any accumulation of round cells or plastic material in any section; a heavy eosin stain does not bring out more fibrin or albuminous material than would be expected in aqueous reformed after evacuation. What fibrin is present is almost entirely in the lower half of the chamber and disposed along its walls.

"The sinus angle above is wider than that below; the cut end of the iris stump does not reach the equator of the lens anywhere and consequently the iris above has been displaced backward into a position that is even more nearly at right angles to the optic axis than in a normal eye. The iris below is thrown forward so as all but to touch the base of the cornea in many sections; indeed, some anterior root synechia to the back portion of the trabeculum corneosclerale has taken place in the sections which go through the angles just a little temporal to the iridectomy area; sections still more temporal are again perfectly free from any evidence of union between the periphery of the iris and the back part of the trabeculum corneosclerale. Both surfaces are perfectly smooth and sharply defined in all except a few peripheric sections (as, for instance, section 49) which show good-sized pigment masses.

"The anterior half of the iris, trabeculum corneosclerale and canals of Schlemm are infiltrated with round cells; those in the iris are almost exclusively of the plasma cell type and only moderate in amount; the posterior layers of the iris do not show any considerable amount of cell increase; the stroma pigment cells are considerably disturbed toward the iris root both above and below. In most sections the infiltration about the canals of Schlemm is so dense or the cells so changed that only round heavy-staining nuclei are seen and the type of cell can not be made out. Despite this, the lumina of the canals are free and lined by a well-preserved endothelium in most sections and filled with blood in many; the position of the canals can always be readily made out. Further evidence of plastic inflammation of the iris is furnished by deposits of pigment detritus, clumps and short strips of pigmented cells on the anterior surface of the lens capsule. Their exact location and the relations to the pupil border of the iris are of great importance in any attempt to establish an order of pathogenesis in the findings.

"In the sections which go through the temporal (sections 60-120) or nasal (sections 144-205) portion of the lens capsule the pigmented cells lie in about the center of the portion of the capsule shown and these (vertical) sections go through two areas, each about 5 mm. wide, in the horizontal plane. The central sections (120-144) show no deposits on the center of the part of the lens capsule concerned, but do show deposits more toward the equator of the lens; these central sections go through a pupil area of about two-thirds of a millimeter in diameter. These evidences of posterior synechia, therefore, extend through an area 5 mm. in width and are absent through a zone of two-thirds of a millimeter corresponding to the size of a normal pupil. Furthermore, there was no actual posterior synechia present at the time the eye was removed, because no sections show adhesion betwen the iris and lens; the slight expanse of the iris below (only 3⅓ mm. overlap the lower equator of the lens for a millimeter in section 133) means that the pupil was well dilated at the last. One may conclude, therefore, that there was first formed a central posterior synechia in a zone corresponding to the position of the sphincter at a time when the pupil was small, and that this was later broken up by dilatation of the pupil and did not reform. These facts are in keeping with the clinical history.

"The ciliary body is markedly atrophic; the processes are all directed forward and much flattened down against the muscular portion of the body. The muscle has lost its triangular form and instead of a prominent angle on the inner anterior face, it presents a very flat curve extending forward from the region of the equator of the lens forward to the canal of Schlemm. ABSTRACT OF DISCUSSION

Dr. S. D. Risley, Philadelphia: I have no adverse criticism to express concerning the treatment pursued, but I think that there is opportunity for another opinion than that given in the paper, as to the nature of the case. This man was free from arteriosclerosis. He was a healthy man, 31 years of age. The attack came on suddenly, without clinically recognized cause, and throughout the subsequent history of the case the different manifestations are, to me, unique. It is only when we come to the laboratory study of the enucleated eye that we get any light on its essential nature. The hemorrhages, which occurred, it should be borne in mind, only after the increase in tension came on, throw some light on the case. Whether the intraocular hemorrhage shall occur, as has been suggested here, during the period of low tension, or whether it shall occur with very high tension depends altogether on which set of vessels furnish the hemorrhage—the arteries or the veins. If we let up the tension very suddenly in a glaucomatous eye with high tension, by iridectomy or otherwise, it is natural that we should expect hemorrhage from a rupture of the retinal arteries or arterioles, whereas the higher the tension the greater the engorgement of the venous system of the eye becomes and therefore venous hemorrhage is more and more imminent. This man had no arterial disease, but the pathologic study of the ball shows that there was unquestionably a chronic iridocyclitis, *e. g.*, there was a deposit on the anterior capsule of the lens, left undoubtedly by delicate synechiæ which were torn loose with the dilation of the pupil when the high tension came on. It was at this point in the clinical history that the blood leaked through the pupil into the anterior chamber, pressed forward by the increase of tension, the hemorrhage being a leakage from the venous system of the eye. I think, therefore, that we are justified in regarding this case, not as one of hemorrhagic glaucoma, associated with sclerosis of the retinal arteries, but glaucoma with hemorrhages from the venous system of the eye. It is therefore separated as wide as the poles from hemorrhagic glaucoma with arteriosclerosis. It is important that we distinguish between them. The diagnosis should be changed to glaucoma with hemorrhages.

Dr. Walter L. Pyle, Philadelphia: Through the courtesy of Dr. Frank, a year ago I had an opportunity to examine this patient. From the clinical history and study of the physical signs at that time, I believed the case to be one of sympathetic affection, and despite the absence of the characteristic microscopic findings described by Fuchs, I am still of that opinion.

Dr. H. Gifford, Omaha: It seems to me that it is altogether premature for us to lay down a microscopic diagram of what we consider to be the findings of sympathetic ophthalmia and say that if the clinical picture, no matter what it is, does not give microscopic findings corresponding with the diagram it is not sympathetic ophthalmia. Remember we do not know what sympathetic ophthalmia is. The idea is wrong. Here is an eye that had abundance of chance to get infected. Several openings had been made. We find the evidence of iridochoroiditis. Whether it was of a kind to produce sympathetic ophthalmia we do not know. We have to diagnose sympathetic ophthalmia from the clinical picture and not entirely from the microscopic findings at the present time.

Dr. E. V. L. Brown, Chicago: I rise to defend my anatomic findings and their significance in this case. First it is true, as Dr. Gifford says, that we do not know the organism which causes sympathetic inflammation, but this does not lessen the value of anatomic facts. The same is true of sarcoma, yet we know when sarcoma is present and when it is not, and from the anatomic facts alone. We must accept Fuchs' statement as to whether the anatomic findings in sympathetic ophthalmia are constant or not. His statement is that in 181 eyes he made a clinical diagnosis either of sympathetic inflammation or of sympathetic irritation and from the anatomic study of these cases made up his mind as to a characteristic anatomic finding. Then, without reference to the clinical histories, he divided the specimens into two groups and, so to say, said of the first group: "Each of these 25 eyes caused inflammation of the fellow eye." And of the second group: "None of these 157 eyes caused inflammation of the fellow eye." Referring then to the clinical records, he found that 24 of the 25 eyes had caused sympathetic inflammation and that none of the 157 had done so. Now, it is true, this is not a constant finding, but in my opinion one must either doubt Fuchs' word or admit he has made a most remarkable contribution. These findings have been corroborated by others and in a recent number of the *Archives of Ophthalmology* Fuchs reiterates his conclusions.

I have shown the specimens of this case to Professor Fuchs as well as to Professors Salzmann and Wintersteiner and to Mr. Treacher Collins and two well-known members of this Section, and my report is made in keeping with the remarks of these men. I would not have had the temerity to present simply my own opinion of the case. Yet I have studied the facts with an open mind. I saw the patient before the eye was removed, and my clinical diagnosis was sympathetic inflammation. The eye had had many openings made into it: there was ciliary injection and there were also precipitates on the back of the cornea of the fellow eye. But many traumatized eyes do not cause sympathetic inflammation, and no one has yet described a picture of the inflammation in the second eye so typical that we may cover the primary eye and diagnose sympathetic inflammation from the appearance of the second eye alone. A perforating wound and precipitates on the back of the other cornea do not make a diagnosis of sympathetic inflammation, and unless we go back to the dark ages we must change a clinical diagnosis when reliable anatomic facts refute it. I hope Dr. Frank will state, in summing up, why he still considers this case one of sympathetic inflammation.

Dr. G. H. Price, Nashville: Dr. Risley called attention to a very significant point in this particular case, when he said it was glaucoma with hemorrhage. It is a well-known physical fact that in a locomotive boiler which has been carrying a pressure of 200 pounds to the square inch and in which the pressure has run down to 30 pounds or less, there may be an explosion due to some defect in the mechanism by which this pressure is suddenly released. Or if in a boiler that is carrying a temperature of several hundred degrees, and a steam pressure of 200 pounds, a valve is suddenly opened which liberates the pressure instantaneously, the water remaining in the boiler, which is above the steaming point, is immediately converted into steam and the result is an explosion of the boiler. This is the same principle of the high-tension hemorrhage in glaucoma when we do an iridectomy; the tension being immediately released, a hemorrhage occurs because the high blood pressure suddenly overfills the vessels, causing the walls to give way, since the restraining influence of the intraocular pressure is lost. There is another very simple physical experiment that perhaps bears some relation to the condition we find present in some of these cases. If we take a flask and fill it half full of water and bring it to the boiling point and allow it to boil a few minutes, and while boiling remove from the flame and cork it, the ebullition ceases. If we then apply cold to the flask the supernatant steam is condensed, the tension lowered and the water boils again. There may be hemorrhages, depending on these two physical principles. In the case reported, it was a low-tension hemorrhage, a venous hemorrhage, and as Dr. Risley has suggested, this in all probability was due to some autoinfection or autointoxication somewhere, and the condition set up in the other eye, for which the enucleation was made, was probably brought about by just such a condition. Now if we had reached the point where we could determine whether we had a glaucoma which was due primarily to a marked increase in tension *per se*, then we would be in a position to determine what was the best procedure. In the case reported by Dr. Bull, of exceedingly high tension, if he had made an iridectomy in that case the chances are that he would have had considerable hemorrhage, due to the sudden release of the restraining influence on the retinal vessels, and so the thing to do was to gradually decrease the tension by paracentesis. But in Dr. Frank's case it was due to an entirely different etiologic factor and the relief of pressure, unless it was total, had no effect on it.

Dr. F. H. Verhoeff, Boston: I have examined many cases of sympathetic ophthalmia and before Fuchs published his work had come to the conclusion that there was a perfectly characteristic lesion. There is one point, however, connected with the histology of it that to me is not absolutely clear. The essential lesions consist of focal collections of lymphoid cells in the centers of which epithelioid and occasionally giant cells appear. Now in the early stage it is a question whether epithelioid cells are present, or if so, whether they could be distinguished from the lymphoid cells. Thus, going by Fuchs' description, when examined in this stage we must say the case is not one of sympathetic inflammation, although strictly speaking we would be wrong. However, I have never seen a case of sympathetic ophthalmitis develop after an eye showing this histologic picture was enucleated, although I have examined many such. At this early stage, therefore, if such it is, it is safe to say that the other eye will not become affected. In regard to Dr. Frank's case, I would like to suggest that the most obvious explanation is that it was a case of serous iritis complicated by glaucoma. Probably the condition had been present sometime without being noticed by the patient. Afterward, as is usual, the other eye became affected.

Dr. Mortimer Frank, Chicago: I accept Dr. Risley's criticism of the title of my paper, but until Fuchs' findings are universally accepted as pathognomonic of sympathetic inflammation I still consider my case one of sympathetic ophthalmia according to the clinical symptoms described in the text-books, and I am willing that the pathologists should fight out the diagnosis by *microscopic section*.

HAIR BALL OR HAIR CAST OF THE STOMACH AND ITS OCCURRENCE IN CHILDREN

REPORT OF TWO INSTANCES WITH BIBLIOGRAPHY AND SYNOPSIS OF CASES REPORTED TO DATE*

W. W. BUTTERWORTH, M.D.
Professor of Pediatrics, Medical Department, Tulane University
NEW ORLEANS

The occurrence of bezoars in various domestic animals is not uncommon and these strange concretions have been esteemed alike for their antidotal properties against poisons, and likewise because of the efficacy or charm they were supposed to possess against the plague, malignant fevers, vertigo, epilepsy, dysentery and other ailments.

Certain concretions likewise occur in man as a result of the ingestion of indigestible substances; thus Tidemand[1] reports a gastrolith or stone, probably of some resinous material and weighing 15 gm. Friedlander,[2] Vonnegut,[3] and Manasse[4] each record cases of gastric shellac calculus, while Ewald[5] quotes an instance of a carpenter who mistook his varnish for liquor and drank it; it formed a gastrolith. Outten[6] has reported a case of double gastrolith.

Concretions of vegetable origin are also occasionally found in the stomach of persons; thus Langenbach[7] and Kooyker[8] relate such instances. In Schreiber's[9] patient, a peasant woman, a phytobezoar was found at operation. The mass was composed of the fibrous roots of a plant (*Schwarzwurzel*) which is said to be a popular remedy for all sorts of ailments in Germany.

In Quain's case[10] a mass weighing 4 pounds and consisting chiefly of cocoanut fiber was taken from the stomach at autopsy. It had caused perforation and peritonitis. More fortunate was a woman mentioned by Capelle[11] who vomited a foreign body formed exclusively of vegetable débris and thus discredited a diagnosis of cancer of the stomach which had been made.

The most remarkable of these singular concretions, however, is the hair ball, or, more correctly speaking, the hair cast of the stomach, and sometimes of the intestines also, and, while they can not be called rare conditions, at least they are of infrequent occurrence, for, after a somewhat thorough search, I am able to find only 42 cases recorded to date. Oddly enough thirty-nine of the patients were females, the youngest of whom, my patient, was 8 years old at death, while the oldest person was an insane man, aged 43.

Curiously enough, very few instances of trichobezoar are found reported in German literature, the habit of eating hair apparently being more prevalent among English-speaking people, which led Bussell to say that "the eating of hair seems to be a favorite occupation of English women."

The history of my patient is as follows:

CASE 1 (BUTTERWORTH'S).—*Patient.*—Pearl F., white, aged 8, a native of Mississippi. Her father is living and well at 53; her mother living, 38 years old, has had bowel trouble all her life and does not enjoy good health. They have had eight children: Pearl, the subject of this history, and seven who are living. All look sickly, except the two oldest girls, 16 and 19 years old, respectively. The five younger children are boys and are 4, 6, 8, 11 and 13 years old; they are anemic and emaciated, but are never sick in bed. Examination of their feces show that seven of the nine members of the family have hookworm infection.

History.—The patient was sickly from birth until about 2 years of age, after which time she was in apparently good health, though pale and anemic all her life. She had ground-itch every summer since the age of 3. She was not so well for the last two years, though she had no definite ailment. A little more than a year before her death she complained of extreme weakness; would vomit frequently, but never any blood. The stools were dark in color and contained much mucus. She was known to eat sand and dirt for several months prior to her last illness. Not a member of the family suspected that she was eating her hair, which was worn long and loose over her shoulders. Her mental condition was not abnormal, yet she had odd ways peculiar to herself. She was very shy and secretive, good-natured, very placid and seemed to lack power of concentration.

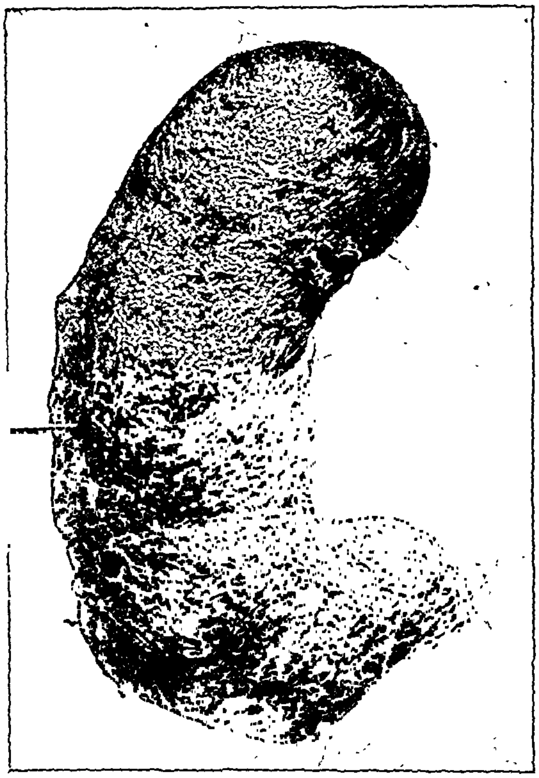

Fig 1.—Hair cast of stomach. Butterworth's case.

Present Illness.—The patient had complained of abdominal pain for about two weeks, when she was seen (Nov. 3, 1908) by Dr. N. W. Fountain of Nicholson, Miss., to whom I am indebted for these notes. He discovered a firm crescent-shaped swelling in the epigastric region. The temperature was 104 F., respiration 40, and pulse 148 per minute. The patient was twice given a cathartic without satisfactory results. On the fourth day of her illness, 12 grains of calomel with soda were given, after which she had several loose copious movements. Temperature dropped to normal, respiration to 20 and pulse to 108. On the fifth day the blood was examined and tertian malarial organisms were found. The feces contained an immense number of uncinaria ova. The patient was given quinin, phenacetin and stimulants.

Examination.—The patient entered the Charity Hospital (New Orleans, La.) on the eleventh day of her illness, when it was noted that she was very weak, emaciated and anemic. She rested on her side in bed with the knees bent and thighs flexed on the abdomen. All visible mucous membranes were pale. Examination of the chest was negative except that there was a pronounced hemic murmur. The abdomen was distended, somewhat tender and tympanitic. There was a firm somewhat irregular cucumber-shaped swelling occupying the epigastric region and losing itself in the hypochondriac region of the left side. The mass was only very slightly movable; firm continuous pressure caused slight indentation for a time. The child complained of pain after manipulation. The liver was slightly enlarged; the lower border was palpable one inch below the costal border; it was not sensitive; was smooth and hard. The spleen was not palpable in its normal region. There was considerable edema of the feet and legs. The urine was negative for sugar, albumin and indican, but contained a small amount of pus with hyaline and granular casts. Numerous uncinaria ova were found in the stools, as well as blood and pus. The blood was free from plasmodia. Hemoglobin was below 15 per cent.; leucocytes, 20,000 per cm. Differential count:

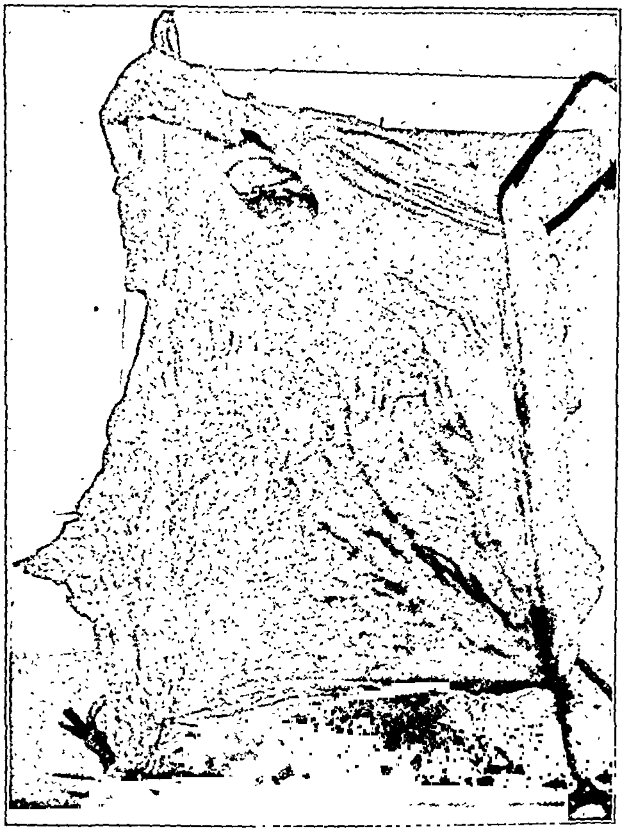

Fig. 2.—Stomach, Butterworth's case, showing ulcer.

Large mononuclears, 4 per cent.; small mononuclears, 13 per cent.; polynuclears, 81 per cent.; eosinophiles, 1 per cent.; transitionals, 1 per cent. Polychromotophilia, poikilocytosis and normoblasts are noted in the report. A von Pirquet test was negative.

Course of Disease.—The patient's condition was such that an exploratory operation was not considered justifiable. During the last two weeks of life she ran a constant temperature usually between 100 and 101; had a fairly good appetite; had daily several dark-colored, offensive stools containing mucus and blood. She was not nauseated, neither did she vomit. At times she complained of severe abdominal pain, which was paroxysmal in character and was so violent that it caused her to cry out aloud. She was intelligent and singularly placid. It was remarked later that several of the nurses had observed that she would twine slight strands of her hair (which was rather long and worn loose) around her fingers from time to time. No one saw her put any hair into her mouth and her family denied all knowledge of the habit. Examination of her scalp after death, however, showed several irregularly bald patches. She gradually grew weaker, became delirious, edema increased, and death occurred after an acute illness of twenty-seven days. Thymol was given on three occasions with negative results. In this connection it is to be noted that when the stomach was opened at autopsy, the contents, viz., mucus, food and hair ball, had a pronounced thymol odor. The last course, 15 grains, divided in two doses and given one hour apart, was taken forty-six hours before death.

Autopsy.—This was held by Dr. O. L. Pothier, pathologist to Charity Hospital, an abstract of whose report follows:

Body of white female child, which was still warm and was anasarcous. The lungs and heart were apparently normal. The abdominal cavity was found to contain fluid which seemed to be purulent. The stomach was filled with a hard mass which was resistant to touch, and measured 16 x 8 x 5.5 cm. On section a mass of hair was found which filled the whole cavity of the organ and resembled a cast of viscus. It was free in the stomach and was not adherent to any portion of the mucous membrane, which was covered by a thick coating of glairy mucus. In a dry state the hair cast, which was a fairly accurate mold of the stomach, was 4 inches wide at the esophageal end and had a fairly uniform thickness of 1¾ to 2 inches. It weighed, dry, 3¾ ounces, and was composed of human hair of a texture and color corresponding to patient's. Many of the hairs measured 15 to 18 inches in length. Incorporated throughout the mass were small particles of husks of grain and fruit. The mucous membrane of the stomach was normal except at a point 2 cm. from the pyloric extremity and along the lesser curvature and anterior wall of the organ. At this point there was a chronic circular ulcer about one inch in diameter which formed an abscess cavity and which was firmly adherent to the under surface of the right lobe of the liver. Pylorus and cardiac extremities were patulous. On examining the small intestine, several hundred uncinaria were found imbedded in the mucous membrane; very few were present in the duodenum, the greater number being in the jejunum. They progressively diminished in number in the ileum, none being found beyond the middle third of this portion of the intestine. There was considerable blood and mucus in the small bowel. The mucous membrane was of a shaven-beard appearance, and presented many points of punctate hemorrhage, particularly in the jejunum. The spleen was adherent to the diaphragm and to the posterior wall of the abdomen, and presented two superficial gangrenous areas, one at the lower pole which measured 4.5 by 3 cm.; the other along the anterior border and upper pole measured 8 by 2.5 cm. The kidneys and liver showed a parenchymatous degeneration.

The habit of swallowing hair is most often commenced in early life. Lyons[12] relates that a boy, 2 years of age, would pick at the carpet, woolen garments or anything of a hairy nature. He had convulsions; was given a cathartic, and passed by rectum a ball of hair about the size of a silver dollar, together with some smaller masses. He had no more convulsions. Jacobson's patient[13] acquired the habit at 2½ years of age: Allen's[14] Best's,[15] and Pollock's,[16] and the patient in the British Medical Museum case[17] at the age of 3, while it is recorded that Ritchie's[18] and Baudamant's[19] patients had been addicted to eating hair all their lives. In 75 per cent. of the collected cases the patients were known to have acquired this habit during childhood. In the majority of these instances it is not clear why such a perverted appetite existed; it is not noted that the presence of intestinal parasites played any important part in the etiology, for I find only two such instances, my own case and Quain's[10]

The fact that insane persons are addicted to eating foreign bodies has led to erroneous conclusions; those addicted to eating hair, almost without exception, are apparently mentally sound; demented subjects usually partake of more solid substances, viz., nails, screws, wood, etc. In this series only four patients were reported insane: those in Cobbold's,[20] Campbell's,[21] Gemmel's,[22] and Osler's[23] cases; and, with the possible exception of the last mentioned, all had such extraneous matter as nails, tacks, leaves, cocoanut fibers and twine, in association with limited amounts of matted hair, removed from the stomach.

In fact, Dandois' patient[24] is the only one reported to have been hysterical, while several narrators expressly state that their patients had good, active minds, and that there was not the slightest suspicion of an impaired mentality.

It is probable that the custom of young girls wearing their hair loose, flowing and hanging over the shoulders, *is an important factor* in favoring the establishment of the practice of biting the hair or passing strands through the mouth, or between the teeth. This is most likely the reason why hair bolus is practically confined to the female sex, and to its greatest frequency at an age corresponding to the period in a girl's life when her hair is worn long and loose.

Various reasons are given in explanation of the abnormal appetite; thus Paton's patient[25] ingested her hair "because it was so nice;" Knowsley Thornton's patient[26] had for years been in the habit of "eating the combings of her hair, and her sewing-cotton ends, to clean her tongue;" while Schönborn's patient[27] confessed that she swallowed hers in order "to make her voice clear;" Jacobson's[13] because she rather liked the tickling sensation produced by the hair in its transit to the stomach; another[28] adopted this method with suicidal intent and failed.

The localization of a trichobezoar is influenced by its size; it can be readily conceived that small tufts or mats of hair may be passed through the bowel. The observation of this fact alone suggested the diagnosis in at least three cases—viz., Thornton's,[26] Harvie's,[29] and Rather's.[30] Others were less fortunate in that the migrating concretion either caused intestinal obstruction (Brewster's[31]) or a *fatal perforation* (Ritchie's [18]).

A small concretion in the stomach will assume a spherical or oval form; with increase of size it becomes molded to the contour of the viscus and may overflow into the duodenum (Bruce,[32] Harvie,[29] Allen,[14] Von Bollinger[33]); and even into the jejunum (Pollock[16] and Baudamant[19]); *less frequently the prolongation protrudes* through the esophageal opening of the stomach. *In only one instance* was a hair ball limited to the esophagus (Gemmel[22]).

Most often only one hair bolus is present in the stomach; when two occur they appear facetted and join each other snugly. Such are reported by Wood,[34] Finder,[35] Russell,[36] and Osler,[23] while Day[37] records the only instance I can find of three distinct trichobezoars occupying the stomach.

These tumors vary in bulk and weight. One of the smallest, Pell-Ilderton's,[38] weighed, dry, 2¼ ounces, or about one-third of its original weight. Several were over 2 pounds; O'Hara's,[39] Baudamant's,[19] Dandois',[24] Swain's[40] weighed 5 pounds 3 ounces, while Mermet d'Hauteville's[41] is reported to have weighed about 6 pounds, and after nineteen days of desiccation weighed 2½ pounds; the latter two are the largest known.

The long-continued action of the digestive juices influences but very little the color or general character of the hair ingested; it has been *explained* (Bell[42]) *that* chemical changes occur in the stomach, with the result of deepening the shade of the hair composing the bolus; while the individual hairs are wonderfully pliant and strong, notwithstanding the influence of digestion, perhaps for years.

It is remarkable how little the general health suffers, considering the duration of the habit; eventually the limit of toleration is reached, and Nature protests. Pain is a *fairly constant symptom*; vomiting at some time or other is usual, and yet, considering the sponge-like and absorbent character of the hair cast, it need occasion no wonder if vomiting should not occur. This happened in my case, and, after seeing the character of the foreign body, I could readily understand that she could not have vomited even had she wished to. Hematemesis is *comparatively rare*, while dyspepsia and an abdominal tumor are usually the earliest and most constant of symptoms.

Alternating attacks of constipation and diarrhea are the usual rule; eventually the breath becomes exceedingly offensive and malodorous; anemia grows more pronounced, ingestion of food more difficult, emaciation and weakness more noticeable, and, unless surgical measures are instituted, with rare exceptions (Rather,[30] Stover[43]), death occurs from *inanition or perforation*.

Cancer of the stomach was the most frequent diagnosis; then followed a displaced spleen, floating kidney, fecal impaction in transverse colon and omental tumors.

In 33 cases in which the final results are obtainable 1 patient died following laparotomy, 16 recovered after

operation, 6 died of peritonitis and perforation, 10 died of inanition.

In only five of these cases was a correct diagnosis made prior to operation, viz., Harvie's,[29] Bell's,[42] Paton's,[25] Thornton's,[26] and Stelzner's,[44] and it is to be remarked that the judgment of these men was almost entirely influenced by a knowledge of similar cases. An exploratory operation revealed the true nature of the swelling in several, while 50 per cent. went to the autopsy table for a final solution.

In the light of my recent personal experience I am inclined to think that a most important element in the recognition of these otherwise puzzling abdominal tumors is a fairly active imagination of this condition which occurs most often in young female children.

I append a brief synopsis and bibliography of all cases reported to date, a total of forty-two.

Case 2 (Wood's).—This case is given from the personal recollections of Dr. Hummel: A child, aged about 7 or 8, was accustomed to eat dirt. The parents, having become aware of this habit, were accustomed to shut the child in a plastered room when it was impossible to keep it under observation. The child began to pick the plaster from the wall and ingest it. This went on for quite awhile. The child became cachectic and lingered in an anemic condition with gastrointestinal disturbances for perhaps a year.

Autopsy.—Death finally occurred, and, the symptoms in the case having puzzled the physician, a necropsy was done, and the stomach was found to contain a ball of cattle hair about as large as a hen's egg. It was then recalled that plaster had been eaten by the child, and that the hair found in the stomach had been ingested with the plaster months before.

It may be explained that the house in which the child had been kept was of antebellum days, and that it was the custom of those days to incorporate cows' hair from tanneries in the plaster used on the walls of dwelling-houses in order to give it consistence and to keep it from crumbling. It is readily realized, then, that the child had taken in the hair while eating the plaster from perverted taste. This case occurred in the practice of Dr. Wood of Shelbyville, Tenn., and the narrator merely has rather indefinite recollections of the circumstances of the case, for at the time he was himself a small boy.

Case 3 (Harvie's[29]).—A girl under 10 years, well nourished, always a moderately nervous child, bright in her school studies, began picking at carpets and woolen materials before she commenced to walk. She developed an early desire to pick her hair and swallow it. She was almost completely bald from the habit, and her mother noticed small masses of hair in her stools at odd times for many years. She was taken ill with nausea, vomiting and pain. A sausage-shaped mass was found in the epigastrium, which was thought to be impacted feces. A brisk cathartic was followed by a copious purge which contained a small bundle of hair. This with the previous history led to a diagnosis of probable hair ball.

Operation.—A hair-cast was found, which projected into the duodenum about 1¼ inches. It measured 13 inches along its greater curvature, with a circumference of 7 inches. It was composed of hair of varying length, absolutely black and densely packed. There were no definite areas of ulceration. The patient was discharged on the twelfth day after operation completely recovered.

Case 4 (Rather's[30]).—The patient was a girl 9 years old. At the age of 7 it was necessary to clip the child's hair short to keep her from eating it. She confessed to a craving for it, and would secrete herself and indulge her abnormal appetite. For two years "the stomach was easily outlined by palpation and was seemingly as hard as wood." Every few months the child had severe attacks of vomiting. Finally she was given half an ounce of castor oil every three hours for two or three days, and passed three or four rolls of densely matted hair, 2 inches in diameter and 8 inches long, which had little or no feces mixed with them. There was immediate relief and rapid recovery.

Case 5 (Bell's[42]).—A girl, aged 12, for nearly two years had attacks of vomiting, diarrhea and abdominal pain. The vomitus consisted mainly of frothy mucus, with at times particles of food. Six months before operation she had a very severe attack of vomiting and diarrhea, when a mass was felt in the abdomen, and was thought to be an abscess of the liver. The patient weighed 49 pounds, was very bright and intelligent. At about 3 years of age it was noticed that she had a habit of breaking her hair with her fingers, and some difficulty was experienced in overcoming the habit. A diagnosis of probable hair ball was made prior to operation.

Operation.—A hair cast of the stomach 18.1 cm. long and weighing 702 gm. was removed, and a small detached mass was seized in the intestine. Some of the hairs were found to be 18 inches long. At a second operation a hair cast of the intestine 8 inches in length was extracted. At a fourth operation a section of the small intestine was found riddled with openings and 2 inches of intestine were resected. Other perforations developed, and it was necessary again to resect a portion of the bowel, when a Murphy button was used, which she passed. Six months after she entered the hospital, after undergoing eleven operations, she was said to be "on the high road to recovery."

Case 6 (Paton's[25]).—The patient was an intelligent girl, aged 9, in whom a lump was accidentally found in the epigastric region. As she was known to have eaten hair and other similar substances since she was 3 years old, and had only been broken of the habit recently, a hair ball was diagnosed. There were no gastric symptoms.

Operation.—On opening the stomach, a mass consisting chiefly of the child's own hair, 7 inches long, weighing 7¼ ounces and having the general shape of the stomach, was extracted. The child recovered without a bad symptom. While the case was under observation, the doctor's cat had vomited a small hair ball and this suggested the diagnosis of hair ball in his patient.

Case 7 (Jacobson's[13]).—A girl, aged 11, had gastric disturbance for two and one-half years. She vomited a good deal of frothy mucus, but never at any time any food or blood. She had colicky pain, was constipated and lived principally on milk. A cucumber-shaped mass was noticed in her abdomen one year prior to operation. She was quite nervous; was an exceedingly bright child.

Operation.—A perfect cast of the stomach was removed, which on section was seen to be composed almost entirely of hair, with an occasional bit of string. The cast weighed 15 ounces. Later she admitted that from the earliest years of her life she had been in the habit of biting off the ends of her hair, which was always worn long enough to be brought to her mouth. At first she thought she did it simply because she was nervous, but later she rather liked the tickling sensation produced by the hair in its transit to the stomach. She made a good recovery.

Case 8 (Schopf's[45]).—A girl of 12, from her fifth year on, had been in the habit of biting her hair. About one year before the time of operation, she began to vomit and had colicky pains in the stomach; a tumor appeared and was diagnosed as a floating kidney.

Operation.—(At this time diagnosis was made.) A hair tumor weighing 160 gm. in a dry state was removed. A long process of the hair cast extended into the duodenum. Good recovery.

Case 9 (Brewster's[31]).—A girl of 10 had a habit of chewing the ends of two curls which were long and hung over her shoulders. She was sick for two weeks with what was thought to be indigestion. After repeated and unavailing attempts to move the bowels, symptoms of complete obstruction came on. In the median line over the bladder was felt a sausage-like mass about the size of half a banana.

---

[44] Stelzner: Centralb. f. Chir., 1896, No. 31, supplement, p. 121.

[45] Schopf: Wein. med. Bl., 1899, No. 44, p. 863; abstr. Med. Rec., April, 1900, p. 703.

Operation.—The mass was in the small intestine, and when removed measured 3½ inches long and 4½ inches in circumference. It was composed of long and short hairs firmly matted together. The patient died five hours later.

CASE 10 (STOVER'S[43]).—A girl 11 years of age was in the habit of eating her hair, the temporal region being bald. She was said to have suffered with colicky pains in the upper part of her abdomen for two years. She presented symptoms of incomplete obstruction of the bowels for a period of ten days with rectal tenesmus, and then passed per rectum, with relief of all symptoms, a ball of hair which measured 2 inches in length and 3 inches in circumference.

CASE 11 (ST. GEORGE HOSPITAL MUSEUM[17]).—Gould and Pyle, quoting from the meeting of the British Medical Association, London, 1895, state that in the Museum of St. George Hospital, London, are masses of hair and string taken from the stomach and duodenum of a girl of 10. It is said that from the age of 3 the patient had been eating these articles.

CASE 12 (SCHÖNBORN'S[27]).—A girl, 15 years old, vomited incessantly, and became weak and emaciated. A freely movable swelling occupied, the left half of the abdomen; it was painful at all times. The diagnosis rested between a floating kidney, movable spleen or a growth of the omentum.

Operation.—The stomach was found distended and a mass of hair weighing 281 gm. was removed. It was molded to the form of the gastric cavity and consisted of a network of short hairs felted together. The patient confessed that four years ago she had swallowed the hair in order "to make her voice clear." Recovery.

CASE 13 (DANDOIS'[24]).—A girl, 16 years old, was not in good health from the age of 12, and gradually grew worse, had occasional convulsions, probably had hysteria. A hard swelling was discovered occupying the epigastric region, the motility was something extraordinary; the swelling resembled a fetal head; it was not thought to be the stomach.

Operation.—A compact dirty mass, malodorous and difficult to dislodge, was removed from the stomach; it weighed 1 kilo and measured 45 c.c. from pole to pole; circumference was 25 c.c. It was formed of layers of dark hair of same color as patient's.

Recovery followed.

CASE 14 (ALLEN'S[14]).—A girl, aged 16, had felt an oval and freely movable swelling in the region of the stomach for five or six years. She had lost weight during the last year, had some pain after eating, vomited frequently and had frequent attacks of diarrhea followed by *constipation.*

Operation.—A hair ball removed from the stomach was 17 inches long, including the part that extended into the duodenum, and 8½ inches in circumference at the greater curvature.

After operation patient admitted that she had been in the habit of eating her hair ever since she was 3 years old, and up to two years ago. She had bitten off, pinched or pulled out the hairs which she rolled around her finger into a ball or loop and then swallowed. Recovery ensued.

CASE 15 (VON BOLLINGER'S[33]).—A girl, aged 16, had been complaining for two and one-half years with symptoms of gastrointestinal catarrh, anorexia, vomiting, abdominal pain, diarrhea, insomnia, and finally only liquids could be ingested. A swelling was present in the epigastrium, which was thought to be a malignant tumor. Death resulted from exhaustion.

Autopsy.—The stomach and duodenum were distended with a great mass of hair measuring 55 cm. long and 11 cm. broad. As a child the patient had been in the habit of pulling out her hair and putting it in her mouth, which she must have swallowed.

CASE 16 (KNOWSLEY THORNTON'S[26]).—A girl, 18 years old, presented very few symptoms. There was a sausage-shaped swelling in the region of the transverse colon. Frequent doses of castor oil brought away a small concretion of hair and fecal matter.

Operation (Gastrostomy).— A hair cast was extracted measuring 9 inches long by 2½ wide, and which weighed 2 pounds. A sponge was unintentionally left in the abdomen, which was recovered by reopening the abdomen on the following day. Recovery followed.

The patient had been in the habit of "eating the combings of her hair and her sewing-cotton ends to clean her tongue." This she had done for about twelve years. Probably this is the first authentic case in which a correct diagnosis was made prior to operation.

CASE 17 (RANZI'S[46]).—A young woman had had the habit of swallowing hairs, threads, etc., since childhood. Her symptoms were referable to the stomach, and there was a history of the passage by rectum of a hair ball four years previously. There was a movable tumor in the abdomen.

Operation.—A concretion composed of hair, thread and rubber bands was found nearly filling the stomach and duodenum down to the ascending position. This, when removed, presented a perfect cast of these organs, weighing, after drying, 440 gm. and measuring 22 cm. in the stomach and 44 cm. in the duodenum; in all, about 24 inches.

CASE 18 (BERG'S[47]).—A married woman, aged 26, had suffered for three years with symptoms of dyspepsia and anemia and with attacks of vomiting of glairy mucus. For two years there had been noticed a swelling in the epigastric region, and it had grown more rapidly during the last six months. In the epigastric and left hypochondriac region was a swelling as large as a hand, with a concave upper and a convex lower borborder. It could not be displaced toward the region of the kidney. The spleen was in its normal position.

Operation.—Laparotomy showed that the swelling was in the stomach and was composed of hair, short and long, forcibly compressed. It was removed piecemeal and weighed about 900 gm. Complete recovery ensued.

The mother of the patient said that when about 3 years old she had a habit of chewing hair, but the patient denied having done so since she could remember.

CASE 19 (RUSSELL'S[36]).—The patient was a woman, aged 31. Her health had been good and she had never suffered from indigestion. She had a severe attack of hematemesis. A large swelling occupied the left side of the abdomen and extended into the pelvis. It was thought to be an enlarged spleen. The tumor was first observed when the patient was 14 and had been gradually increasing in size for the last seventeen years.

Autopsy.—The tumor was found to consist of a great mass of human hair, accurately molded to the shape of the stomach in which it lay. It had drawn down the stomach into a vertical position, so that the pylorus lay in the pelvis. The mass of hair was divided into two unequal portions, accurately fitted to one another, constituting a hard solid mass; it weighed 4 pounds 7 ounces, was 12 inches long, 5 inches broad, and nearly 4 inches in thickness. The mass was divided and found to be composed entirely of human hair intermixed with broken-down particles of food. The hairs constituting the tumor coincided exactly with the hair on the patient's head, both in color and in general character. They were of all lengths, up to 20 inches; most of them of the greater length. Not a single root could be found; all appeared to be broken off. A single small ulcer existed in the greater curvature of the stomach, which otherwise was healthy, except that the pyloric orifice was four times its normal diameter.

CASE 20 (MAY'S[48]).—A woman, aged 26, began to suffer pain, about three years before examination, in the left hypochondriac region, and soon noticed a hard swelling near the navel, a little to the left of the median line. When seen the tumor occupied the situation of a distended stomach; it was hard and slightly movable. The patient looked unhealthy, had lost flesh, and vomited occasionally. She gradually became weaker and died from exhaustion.

Autopsy.—The stomach was found adherent to abdominal wall, and in it was a mass of hair composed of numerous small hairs matted together by mucus. The concretion measured 20 inches in its longest and 12 inches in its shortest circumference, and weighed 26 ounces; when dry it weighed 10 ounces.

48. May: Tr. Chir. Soc., London, 1855; Assn. Med. Jour., London, 1855, ii, 1147.

Inquiry revealed the fact that the patient had been in the habit of swallowing her hair ever since she was 4 years old, a period of twenty-two years. She did not exhibit any trace of mental alienation.

Case 21 (Pollock's[16]).—A young woman, aged 18, had always been delicate, but more so during the last year. For several months she had been suffering from a swelling, about the size of an orange, in the epigastric region. It was not painful on mild pressure, was apparently solid and slightly movable. Following a paroxysm of vomiting she complained of much pain; this recurred on the following day and soon afterward she collapsed and died.

Autopsy.—There was evidence of recent peritonitis. A mass was removed from the stomach and duodenum, which consisted chiefly of long black hair and pieces of strings matted together. That taken from the stomach had a length of 6 inches, a width of 3¾ and a thickness of 2½ inches. The duodenal mass extended into the jejunum; it was 14 inches in length and 2¼ inches in diameter. It appeared that the patient had been known to eat hair since 3 years of age.

Case 22 (Ritchie's[18]).—This was reported by Dr. Steele. A factory woman, 21 years old, had severe and painful vomiting with alternating constipation and diarrhea. A hard swelling was found occupying the whole epigastric space. It was not discovered until after her death that the patient had all her life evinced a morbid appetite for chewing human hair.

Autopsy.—A hair mass was extracted from the stomach, which weighed 21 ounces. It was devoid of a nucleus and seemed composed chiefly of human hair, with here and there small remnants of thread and sponge closely agglutinated with mucous secretion. Near the ileocecal valve, two smaller masses were found, weighing, respectively, ½ ounce, and 1½ ounces, and having the same distinctive characters as the one already mentioned. That portion of the intestinal canal lying in close approximation with the lower concretions were found disorganized and perforated.

Case 23 (Mermet d'Hauteville's[41]).—A girl, 17 years old, often had abdominal pain and irregular fever; had vomited more or less constantly for three years. A swelling of large size of the contour of the stomach and freely movable was present in the epigastrium. She died of inanition.

Autopsy.—On opening the stomach a compact mass of hair was seen extending from the esophagus to the upper jejunum; the central core consisted of the kernel of a nut. The mass was of the same color as the patient's hair. She was almost bald. When first removed, the hair cast weighed about 6 pounds, and after 19 days of desiccation weighed 2½ pounds.

Case 24 (Baudamant's[19]).—This is the earliest reported case of hair ball. It occurred in a boy 16 years old, who was seemingly unable to resist the impulse to pull out and swallow his own hair and that of others also; it is reported of him that he ate all the hair he could find. He had diarrhea, frequent and violent vomiting and fever. An oval mass could be felt a little below the pit of the stomach which became very painful. He died of exhaustion.

Autopsy.—Two masses of hair were discovered; the largest of these filled the stomach and extended throughout the duodenum; this had a cherry-stone for its nucleus. The smaller mass was in the jejunum. The combined weight was 2 pounds and 1 ounce. When dry they weighed 11½ ounces.

Case 25 (Siraud's[49]).—A girl of 16 presented very few functional signs. A hairy mass was removed from the stomach, which weighed 765 gm. and measured 28 c.c. by 7 c.c. in width. The condition had been diagnosed as fibroma, tuberculous peritonitis, splenomegalia or cyst of the pancreas.

Case 26 (Stelzner's[44]).—A young woman 18 years old, habitually bit off the ends of her own hair and of other girls also.

Operation.—Stelzner, who knew of Schönborn's case, suspected hair-ball prior to operation. A hair-ball weighing 180 gm. and the size of a goose egg was found at operation. The patient made a good recovery.

Case 27 (Swain's[40]).—A woman of 20 had had almost daily attacks of vomiting during the last five years. There was a large abdominal swelling, well defined, solid and very movable laterally. It stretched obliquely across the abdomen from the left costal border down into the pelvis; the fingers could be passed around the lower border, between it and the pelvic cavity. It was continued up behind the left costal cartilage by a thick pedicle apparently about 10 or 11 inches in circumference. There was no tenderness on pressure. A tentative diagnosis was made of tumor of omentum or a splenic enlargement.

Operation.—The mass was removed piecemeal from the stomach. Mucous membrane at the pyloric end was studded over with circular patches of granulations about the size of a shilling. Cardiac extremity was healthy. The concretion weighed 5 pounds, 3 ounces. Recovery ensued.

It was recalled that at one time the patient had had a very fine head of black hair, which fell below her waist, and it was noted that on three occasions during her illness she became quite bald.

Case 28 (Cobbold's[20]).—An idiotic, epileptic and hydrocephalic boy of 18 had been in very poor health for more than a year when obstinate vomiting set in, and he died from exhaustion.

Autopsy.—The peritoneum showed no signs of inflammation; the stomach was enormously distended and contained an elongated ball of human hair and horse hair, all closely matted together. The mass in its wet state weighed 2¼ pounds. There were no signs of irritation, inflammation or ulceration of the mucous membranes of the stomach or intestines.

Case 29 (O'Hara's[39]).—Reported by Herman Schlesinger. A woman, 22 years old, was delirious following an attack of grip, during which time she ate her hair. There was no gastric trouble other than continued pain. A swelling was present, about the size of a cocoanut, which was freely movable. This had been diagnosed as a hydatid cyst or a movable kidney.

Operation.—A hair ball was found which filled the stomach and which weighed two pounds. Good recovery.

Case 30 (Wood's[34]).—A young woman of 22, always healthy until about the age of 18, had symptoms of chlorosis, vomiting, constipation, and abdominal discomfort resembling labor pains; passed a small lump of hair by the bowel.

Autopsy.—The abdomen contained a large quantity of dark-colored fetid fluid. Except for the stomach, the organs were normal; the stomach contained two lumps of hair which nearly filled the viscus. The hair in color and texture seemed much like the patient's own, which was noticed to be very short. The total weight of casts when dry was 16½ ounces.

Case 31 (Wren's[28]).—A widow, aged 23, had complained for three months of almost constant pain in the epigestric region, with occasional vomiting. Examination revealed a movable swelling extending down to within one inch of the umbilicus, and up under the ribs and ensiform appendix. Malignant growth was suspected.

Operation (Gastrostomy).—A large mass of hair was delivered from the stomach which weighed 13½ ounces and measured 7½ inches by 5 inches by 1¾ inches thick. After drying, the cast weighed 4 ounces.

The patient afterward stated that because of an illegitimate pregnancy she tried to commit suicide. She pulled her hair out, and swallowed it for that purpose. If so, the hair had been in the stomach for two years and seven months.

Case 32 (Bruce's[32]).—In a non-hysterical woman, aged 26, two months prior to the birth of her child, a swelling which gave no symptoms, was discovered in the left hypochondrium. Twin pregnancy was suspected. The mass persisted after delivery and it was then thought to be a displaced spleen.

Operation.—A hairy mass was removed from the stomach, which weighed 23 ounces and measured 24 inches long and was two inches in diameter, coming to a point in the duodenum into which it extended about 6 inches. The cast consisted entirely of hair twisted and intimately woven together; of a brownish color, and exactly the same shade as that of the patient's. Single hairs were dissected out, ten and twelve inches in length.

Case 33 (Thorburn's[38]).—Reported by Pell-Ilderton. A woman, aged 29, for more than two years had had more or less vomiting after meals; she could usually keep food down if she remained in a recumbent position. The pain was persistent. A mass could be felt in the epigastrium, extending over into each hypochondrium, which rose and fell with respiration, and was freely movable. The patient's hair was scanty and was about 3 inches long.

---

[49] Siraud: Soc. de chir. de Lyon, 1901; reported by Cathelin, Bull. Soc. anat. de Paris, 1902, iv, 107.

Operation.—The stomach was opened and a hair ball, in form and contour resembling this organ, was removed. It weighed in the dry condition 2¼ ounces, and measured, length 3¾ inches, depth 2¾ inches, width 1¾ inches.

After the operation the patient was occasionally caught eating her hair, and she admitted having been addicted to the habit ever since she had scarlet fever, fourteen years before.

Case 34 (Best's[13]).—A woman, aged 30, had begun to suffer pain in the stomach at the age of 15, but was able to continue her duties as a domestic until the age of 24. From that time on she was constantly under treatment. A hard nodular tumor could be felt in the epigastrium which was thought to be scirrhous cancer of the stomach. This she stated increased in size. While at work in a harvest field she fainted from violent pain in the abdomen and died seven weeks later.

Autopsy.—A large concretion of human hair was found in the stomach and lower part of the esophagus, forming a mold of the cavities. The mass weighed 30 ounces avoirdupois. Death was due to peritonitis. There was perforation of a chronic ulcer about the size of a shilling, in the posterior wall of the stomach; also three papillomatous excrescences of the mucous membrane existed. These varied in size from a shilling to half a crown. The patient had indulged in the habit of eating hair since the age of 15.

Case 35 (Dickinson's[50]).—Reported by Inman. A woman of 34 died with obscure symptoms. In cleaning her comb she acquired the habit of placing the detached hair in her mouth and swallowed her combings night and morning.

Autopsy.—A hair cast was removed which was matted into a mass of the shape and size of the stomach when distended. The specimen is in the Museum of the Royal Infirmary Medical School.

Case 36 (Schulten's[51]).—A woman, 30 years old, for three years had pain in the stomach and vomited frequently; recently had noticed a hard round swelling in the abdomen. Floating kidney was considered the most probable diagnosis.

Operation.—The hair ball was spherical and weighed 120 gm. It consisted of matted fragments of cow's hair. The patient was engaged in spinning cow's hair and from time to time would moisten the fingers with her tongue and thus ingested small amounts of this material.

Recovery followed.

Case 37 (Carver's[52]).—Reported by Sir William Gull. A married woman of 32, of vile temper and intemperate habits, otherwise mentally normal, became pregnant and vomited unceasingly until she expelled a seven months' fetus. An offensive vaginal discharge continued with intense pain in the abdomen for two days, when she died from peritonitis.

Autopsy.—In the stomach was found a large mass of hair which extended through the pylorus into the duodenum, perforating the small intestine. The concretion consisted of string, thread, cotton, wool and hair of three colors; the latter could be recognized as belonging to the patient and her two children. The weight of the mass when dried was 5¾ ounces.

Case 38 (W. S. Cooper's[53]).—Reported by Finder. A young woman, who had been insufficiently fed in her youth, suffered great pain which was intensified on the slightest movement. She was unable to take nourishment and there were constant efforts at vomiting. A swelling was distinctly seen and felt in the upper abdomen; the mass was hard on palpation. She was supposed to have a malignant tumor and died of exhaustion.

Autopsy.—In the stomach were found two masses whose combined weight was 16 ounces. The concretions were composed of human hair and horse hair, sewing-thread, grasses and plant fiber. Two deep ulcers had almost perforated the stomach.

The specimens are in the Pathologic Museum of the College of Physicians, New York.

Case 39 (Day's[47]).—A woman, aged 37, a brushmaker by occupation, for about three years had noticed a swelling in the left hypochondrium which was slowly increasing in size. The patient had been treated for ulcer of the stomach with hematemesis six years before. She complained of dull aching in the stomach, with occasional acute paroxysmal attacks, accompanied by nausea without actual vomiting. The swelling, which lay just under the left hypochondrium, was as big as a cocoanut, and felt trilobate. Cystic disease of the spleen was diagnosed.

Operation.—The stomach was incised and three separate masses of matted hair were found. They were facetted and evidently shifted their position occasionally. They consisted of black bristles, such as she was in the habit of using for making brushes. Recovery was uneventful.

Case 40 (Campbell's[21]).—A woman, aged 23, had been insane for several years; was thought to have phthisis because of her emaciation and general weakness. She vomited frequently for several weeks before death.

Autopsy.—There was no tuberculous deposit in the lungs. In the stomach was found a mass containing matted hair, portions of blankets, and a hank of fine brown twine unwound. Two feet of this twine extended through the pyloric orifice ito the small intestine.

Case 41 (Gemmel's[22]).—An insane man, 43 years old, had swallowed several foreign bodies, including nails. Vomiting and pain followed. To the left of the median line in the epigastrium, there was a lump, about the size of a duck's egg, which was firm and movable.

Operation.—Gastrostomy was performed and 192 nails, half of a screw nail, a piece of brass wire, a carpet tack, several small pieces of stick, a button and a mass of hair, matted and nearly two inches in length, were removed. The concretion of hair was withdrawn from the lower end of the esophagus from which it was projecting into the stomach.

The patient died.

Case 42 (Osler's).—Photograph and specimen are in the Royal Victoria Hospital Museum, Montreal. A personal communication (Feb. 22, 1908) from Dr. Maud C. Abbott, Curator, Royal Victoria Hospital Museum, Montreal, Canada, says the specimen "consists of two large masses of hair placed end to end and together forming a complete cast of a greatly dilated stomach. It was removed postmortem from an insane woman. The diagnosis was not made before death, though it must have formed an enormous tumor in the epigastrium."

609 Macheca Building.

ABSTRACT OF DISCUSSION

Dr. John Ruhräh, Baltimore: While hair-ball is very rare, the habit of eating hair is not uncommon. I have frequently seen cases in which children have eaten hair. In one case the patient was the child of a physician who brought me something which he thought to be some sort of a parasite. On examination I found that it was hair and the child was carefully watched and the habit broken. Two other cases that I have seen were in hospital patients who ate the hairs which they picked from the blankets.

Dr. R. B. Gilbert, Louisville: Did the hookworms found in Dr. Butterworth's case have anything to do with the pathology? Another peculiar thing about such a case is that these hairs are not carried down through the alimentary tract by the solid food taken. It seems that the child eats only a small portion of hair each day and yet the hairs remain in the stomach instead of passing through. Were any of these hairs found in the lower portion of the intestinal tract? This is the first case of hair-ball in the stomach of a human being that I have ever seen. It is certainly an interesting and rare case, and doubtless many of these cases go to autopsy without a diagnosis.

Dr. W. W. Butterworth, New Orleans: I have appended to this paper all the known cases of hair-ball reported to date. In one instance a physician found a tumor in the epigastric region, prescribed a half-ounce of castor oil every three hours, and after two or three days the hair was passed by rectum. There are other instances of similar casts being passed with the fecal matter. It is likely that picking at hairy

---

50. Inman: Med. Times and Gaz., London, July 3, 1869, ii, 6.
51. Schulten: Centralb. f. Chir., 1896, xxxi, 68; Finska läk. sällsk. handl., September, 1895, xxxvii, No. 9, 1897, ii, 289.
52. Gull, Sir William: Tr. Clin. Soc., London, 1871, iv, 180.

and woolen material is common in infancy and early childhood, and undoubtedly many of these cases give rise to no symptoms. The foreign matter passes through the stomach into the intestinal tract and is carried off without further discomfort.

These concretions (hair casts) may or may not have a nucleus of some hard substance, such as a cherry stone or other fruit seed. In my case, section of the mass disclosed nothing of this sort. The tumor was limited strictly to the stomach. In a case reported by Dr. Knowsley Thornton he states that the mass extended up into the esophagus quite a distance. He facetiously remarks that if the patient had lived long enough, a diagnosis could have been made without the slightest difficulty, because the mass would have protruded from the mouth.

The occurrence in my case of uncinariasis with hair-ball made me wish to know if there were any relation between the habit of hair swallowing and the presence of intestinal parasites. It is well known that children harboring the latter have an abnormal and perverted appetite; they eat all sorts of things. It is interesting in this connection to note that in only one other case (which was reported by Quain) was the patient said to have worms. Oddly enough, these interesting and unusual conditions seem to occur in series, and I am now anxiously watching for another case of hair-ball to present itself and hope to establish a correct diagnosis antemortem and not, as happened in the present instance, postmortem.

EMANATION OF RADIUM ABSORBED AND RETAINED BY COCOANUT CHARCOAL

AN ADVANCE IN RADIUM THERAPY*

JOHN B. SHOBER, A.M., M.D.
PHILADELPHIA

About two years ago my attention was called to a letter published by Prof. E. Rutherford in *Nature*, Oct. 6, 1906, in which he points out that cocoanut charcoal has the property of absorbing and retaining for some time the emanation of radium, thorium or actinium. In this letter it is stated that cocoanut charcoal retains the emanation at ordinary temperatures, for Professor Rutherford finds that the emanation retained in charcoal in a tube open to the air loses its activity at the normal rate observed in sealed vessels. Further, he says:

> In a recent investigation I had occasion to pass the radium emanation through a tube filled with cocoanut charcoal, and was surprised to find that the emanation was completely absorbed by it. If a slow current of air, mixed with the emanation of radium, thorium, or actinium, is passed through a tube filled with charcoal, the issuing gas is completely deprived of emanation. This occurs at ordinary temperatures, and there is no necessity for initial cooling of the charcoal.

Impressed by these interesting observations of Rutherford, I at once thought that here was a certain and practical means of utilizing the emanations of radium and other radioactive salts, internally as well as externally, and a practical method of testing the therapeutic value of emanation treatment in various diseases. For a long time the medical profession has felt that the administration of radioactive solutions internally might be followed by pronounced beneficial results in certain diseases, and many efforts have been made to induce radioactivity in water, but only with partial success.

Dr. William James Morton of New York has done much work along this line and has finally decided that the best method of producing radioactive water is to immerse 50 to 100 pounds of a high-grade pitchblende in a vessel of water and has found that the measure of radioactivity of this water is about one-tenth to one-half that of metallic uranium; a very low degree of radioactivity. He dispenses this water to patients who are taking *x*-ray or radium treatment and claims to have cured in eighteen days a man suffering with a small rodent ulcer of the face by the administration of this water and small doses of bisulphate of quinin. The rate of decay of the radioactivity of water, however produced, is very rapid, falling to one-half in a few hours and no trace remaining after a few days.

Since the spring of 1906 I have been occasionally using water prepared in the same way, but can not claim to have observed any pronounced results following its administration. A recent report from the Randal-Morgan Laboratory of Physics of the University of Pennsylvania on the measure of activity of this water gives the following figures:

The water was sent to the laboratory on March 29, 1909.

March 29, activity = 0.1 of uranium disc.
March 30, activity = 0.11 of uranium disc.
March 31, activity = 0.1 of uranium disc.
April 2, activity = 0.07 of uranium disc.
April 6, activity = 0.03 of uranium disc.

It is now generally admitted that the healing and curative properties of many well-known springs is due to the radioactivity of the waters and not to the salts which they may contain. No matter how carefully reproduced artificially, they have not the same therapeutic value, and, even when the original water is shipped from the source of supply, it loses its efficacy. We now know that this is due to the fact that the radioactivity is lost in a few days.

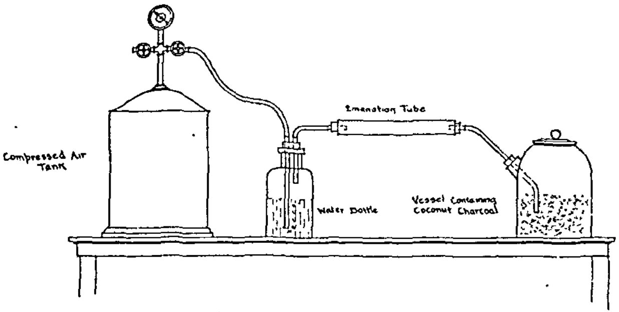

Fig. 1.—Apparatus used in original experiment.

The radioactivity of all spring waters and of radioactive water artificially produced by any method, such as that of Morton, is due to the amount of emanation the water is able to absorb. We know that water will absorb a very small amount of emanation and is able to retain it for but a short time. If, therefore, we can find any substance which can be administered internally and which will absorb and retain all the emanation from a given quantity of a radioactive salt, it seems to me that a great advance will have been made and that we shall be in a far better position than we have ever been before to observe the effect of radioactivity on metabolism and to note its therapeutic value.

Acting on the hint obtained from Rutherford's letter above referred to, on Feb. 19, 1909, I started my first experiment.

Through the courtesy of Powers-Weightman-Rosengarten Company of Philadelphia, I was supplied with a quantity of purified cocoanut charcoal. I had an emanation tube made by H. Lieber of New York. This is a celluloid tube about 8 inches long and ¾ inch in diameter, coated on the inside with a collodion solution containing 1 mgm. of strong radium bromid. Through this tube I passed a slow current of air into a porcelain vessel containing a quantity of cocoanut charcoal (Fig. 1). I found the charcoal to be strongly radioactive, discharging my electroscope more rapidly than would a specimen of high-grade pitchblende ore. I then spread a quantity of this charcoal over a key on an x-ray plate and obtained a very strong picture of the key after an exposure of four days (Fig 2). As a control I tested untreated charcoal on the electroscope and on an x-ray plate, with negative results.

---

* Read before the Maine Medical Association, at the Fifty-seventh Annual Meeting, held at Portland, June 16-17, 1909.

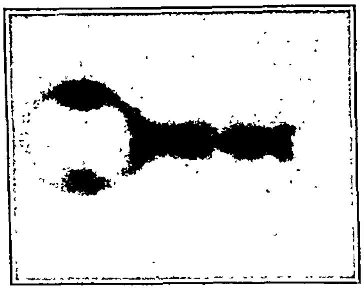

Fig. 2.—Radiograph of key obtained by exposure to radioactive charcoal for four days.

I now felt that it was important to obtain accurate and reliable measurements of the degree of radioactivity to which cocoanut charcoal could be raised and its rate of decay, and I therefore applied to Prof. Arthur W. Goodspeed of the University of Pennsylvania, at whose request Mr. D. H. Kabakjian, of the Randal-Morgan Laboratory of Physics of that university, kindly consented to undertake the work. I supplied Mr. Kabakjian with 1 gm. of 1,000 radioactive radium chlorid and requested him to place this in solution and pass a current of air through it into cocoanut charcoal and measure its radioactivity and rate of decay. I herewith submit his report.

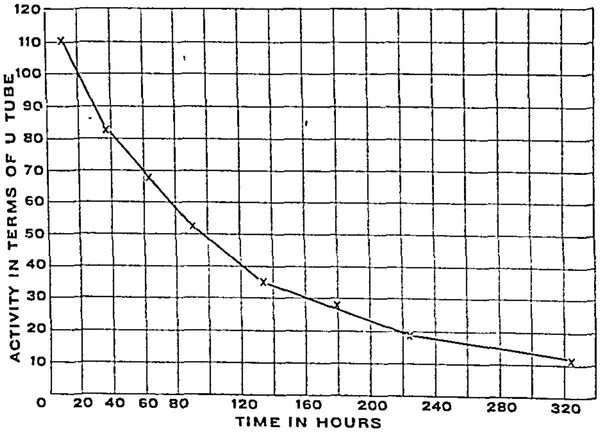

Fig. 3.—Curve showing the decay of activity of radioactive charcoal in sealed tubes.

MEASUREMENTS ON THE ACTIVITY OF COCOANUT CHARCOAL MADE ACTIVE BY ABSORBING RADIUM EMANATION

PREPARATION OF THE ACTIVE CHARCOAL

About 12 gm. of powdered charcoal were divided between two U-tubes, which were connected with each other and also with an aspirator.

One gram of radium chlorid of 1,000 activity was put in a test-tube. Through one of the holes of the two-holed stopper of this test-tube a thistle-tube was introduced which almost touched the bottom, while another glass tube made connections at the top with the U-tubes. A little water was put into the test-tube, just enough to dissolve the radium chlorid, and the aspirator was regulated so as to draw a very slow current of air through the solution (of the radium chlorid) and the U-tubes containing the charcoal. This was kept on for three hours.

The charcoal thus prepared was divided into twelve small tubes and the tubes were sealed. The tubes were opened one at a time at various intervals and their activity compared with the activity of a standard uranium oxid disc.[1] The measurements were made by means of a Dolezalek electrometer, the needle of which was kept charged to 98 to 105 volts, during different measurements, the voltage remaining constant during each particular measurement. The same difference of potential was also applied between the plates of the testing apparatus.

It was found by experiment that freshly prepared charcoal gives out emanation under ordinary conditions which, diffusing into the testing apparatus, greatly interfered with the accuracy of the measurements; for this reason the first two or three readings, often taken in less than two minutes, were regarded as more reliable.

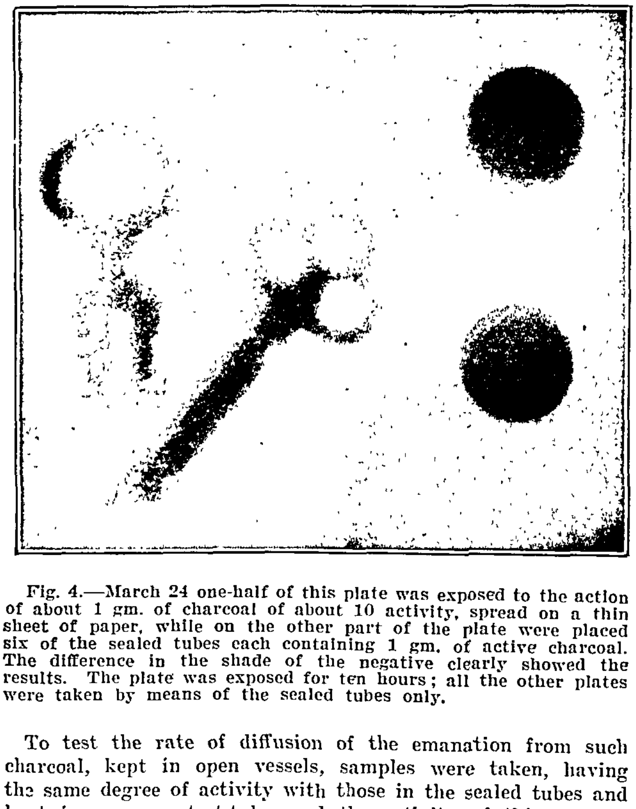

Fig. 4.—March 24 one-half of this plate was exposed to the action of about 1 gm. of charcoal of about 10 activity, spread on a thin sheet of paper, while on the other part of the plate were placed six of the sealed tubes each containing 1 gm. of active charcoal. The difference in the shade of the negative clearly showed the results. The plate was exposed for ten hours; all the other plates were taken by means of the sealed tubes only.

To test the rate of diffusion of the emanation from such charcoal, kept in open vessels, samples were taken, having the same degree of activity with those in the sealed tubes and kept in an open test-tube, and the activity of this exposed specimen was measured under similar conditions. Also one of the samples was divided into two equal parts and one part kept in a sealed tube while the other was kept in a corked test-tube. The results of these measurements are given below:

(1) Wednesday, March 24.

Charge on the needle 98 volts.

Potential difference between the plates of the testing apparatus 98 volts.

12 hours after preparation.

Uranium Disc B

Scale readings.	Time.
28	9 :11 :40
24	9 :15 :50
23	9 :16 :60

Time occupied in passing over 1 cm., t = 64 seconds.

[1] The disc which is used as a standard of comparison in all subsequent measurements is a brass disc 6.7 cm. in diameter coated with a thin uniform layer of uranium oxid. Measurements of activity of water or of charcoal were made on similar shallow dishes or discs.

and woolen material is common in infancy and early childhood, and undoubtedly many of these cases give rise to no symptoms. The foreign matter passes through the stomach into the intestinal tract and is carried off without further discomfort.

These concretions (hair casts) may or may not have a nucleus of some hard substance, such as a cherry stone or other fruit seed. In my case, section of the mass disclosed nothing of this sort. The tumor was limited strictly to the stomach. In a case reported by Dr. Knowsley Thornton he states that the mass extended up into the esophagus quite a distance. He facetiously remarks that if the patient had lived long enough, a diagnosis could have been made without the slightest difficulty, because the mass would have protruded from the mouth.

The occurrence in my case of uncinariasis with hair-ball made me wish to know if there were any relation between the habit of hair swallowing and the presence of intestinal parasites. It is well known that children harboring the latter have an abnormal and perverted appetite; they eat all sorts of things. It is interesting in this connection to note that in only one other case (which was reported by Quain) was the patient said to have worms. Oddly enough, these interesting and unusual conditions seem to occur in series, and I am now anxiously watching for another case of hair-ball to present itself and hope to establish a correct diagnosis antemortem and not, as happened in the present instance, postmortem.

EMANATION OF RADIUM ABSORBED AND RETAINED BY COCOANUT CHARCOAL

AN ADVANCE IN RADIUM THERAPY*

JOHN B. SHOBER, A.M., M.D.
PHILADELPHIA

About two years ago my attention was called to a letter published by Prof. E. Rutherford in *Nature,* Oct. 6, 1906, in which he points out that cocoanut charcoal has the property of absorbing and retaining for some time the emanation of radium, thorium or actinium. In this letter it is stated that cocoanut charcoal retains the emanation at ordinary temperatures, for Professor Rutherford finds that the emanation retained in charcoal in a tube open to the air loses its activity at the normal rate observed in sealed vessels. Further, he says:

> In a recent investigation I had occasion to pass the radium emanation through a tube filled with cocoanut charcoal, and was surprised to find that the emanation was completely absorbed by it. If a slow current of air, mixed with the emanation of radium, thorium, or actinium, is passed through a tube filled with charcoal, the issuing gas is completely deprived of emanation. This occurs at ordinary temperatures, and there is no necessity for initial cooling of the charcoal.

Impressed by these interesting observations of Rutherford, I at once thought that here was a certain and practical means of utilizing the emanations of radium and other radioactive salts, internally as well as externally, and a practical method of testing the therapeutic value of emanation treatment in various diseases. For a long time the medical profession has felt that the administration of radioactive solutions internally might be followed by pronounced beneficial results in certain diseases, and many efforts have been made to induce radioactivity in water, but only with partial success.

Dr. William James Morton of New York has done much work along this line and has finally decided that the best method of producing radioactive water is to immerse 50 to 100 pounds of a high-grade pitchblende in a vessel of water and has found that the measure of radioactivity of this water is about one-tenth to one-half that of metallic uranium; a very low degree of radioactivity. He dispenses this water to patients who are taking *x*-ray or radium treatment and claims to have cured in eighteen days a man suffering with a small rodent ulcer of the face by the administration of this water and small doses of bisulphate of quinin. The rate of decay of the radioactivity of water, however produced, is very rapid, falling to one-half in a few hours and no trace remaining after a few days.

Since the spring of 1906 I have been occasionally using water prepared in the same way, but can not claim to have observed any pronounced results following its administration. A recent report from the Randal-Morgan Laboratory of Physics of the University of Pennsylvania on the measure of activity of this water gives the following figures:

The water was sent to the laboratory on March 29, 1909.

March 29, activity = 0.1 of uranium disc.
March 30, activity = 0.11 of uranium disc.
March 31, activity = 0.1 of uranium disc.
April 2, activity = 0.07 of uranium disc.
April 6, activity = 0.03 of uranium disc.

It is now generally admitted that the healing and curative properties of many well-known springs is due to the radioactivity of the waters and not to the salts which they may contain. No matter how carefully reproduced artificially, they have not the same therapeutic value, and, even when the original water is shipped from the source of supply, it loses its efficacy. We now know that this is due to the fact that the radioactivity is lost in a few days.

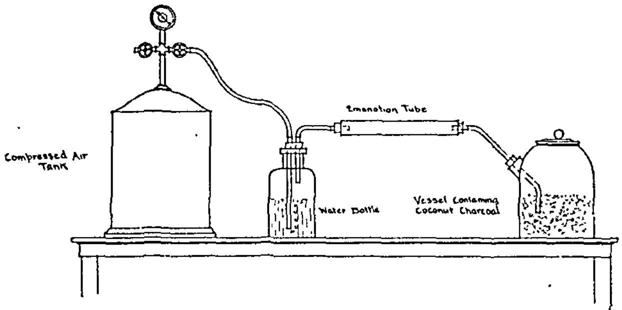

Fig. 1.—Apparatus used in original experiment.

The radioactivity of all spring waters and of radioactive water artificially produced by any method, such as that of Morton, is due to the amount of emanation the water is able to absorb. We know that water will absorb a very small amount of emanation and is able to retain it for but a short time. If, therefore, we can find any substance which can be administered internally and which will absorb and retain all the emanation from a given quantity of a radioactive salt, it seems to me that a great advance will have been made and that we shall be in a far better position than we have ever been before to observe the effect of radioactivity on metabolism and to note its therapeutic value.

Acting on the hint obtained from Rutherford's letter above referred to, on Feb. 19, 1909, I started my first experiment.

Through the courtesy of Powers-Weightman-Rosengarten Company of Philadelphia, I was supplied with a quantity of purified cocoanut charcoal. I had an emanation tube made by H. Lieber of New York. This is a celluloid tube about 8 inches long and 3/4 inch in diameter, coated on the inside with a collodion solution containing 1 mgm. of strong radium bromid. Through this tube I passed a slow current of air into a porcelain vessel containing a quantity of cocoanut charcoal (Fig. 1). I found the charcoal to be strongly radioactive, discharging my electroscope more rapidly than would a specimen of high-grade pitchblende ore. I then spread a quantity of this charcoal over a key on an x-ray plate and obtained a very strong picture of the key after an exposure of four days (Fig 2). As a control I tested untreated charcoal on the electroscope and on an x-ray plate, with negative results.

---

* Read before the Maine Medical Association, at the Fifty-seventh Annual Meeting, held at Portland, June 16-17, 1909.

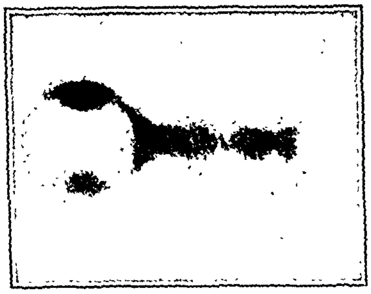

Fig. 2.—Radiograph of key obtained by exposure to radioactive charcoal for four days.

I now felt that it was important to obtain accurate and reliable measurements of the degree of radioactivity to which cocoanut charcoal could be raised and its rate of decay, and I therefore applied to Prof. Arthur W. Goodspeed of the University of Pennsylvania, at whose request Mr. D. H. Kabakjian, of the Randal-Morgan Laboratory of Physics of that university, kindly consented to undertake the work. I supplied Mr. Kabakjian with 1 gm. of 1,000 radioactive radium chlorid and requested him to place this in solution and pass a current of air through it into cocoanut charcoal and measure its radioactivity and rate of decay. I herewith submit his report.

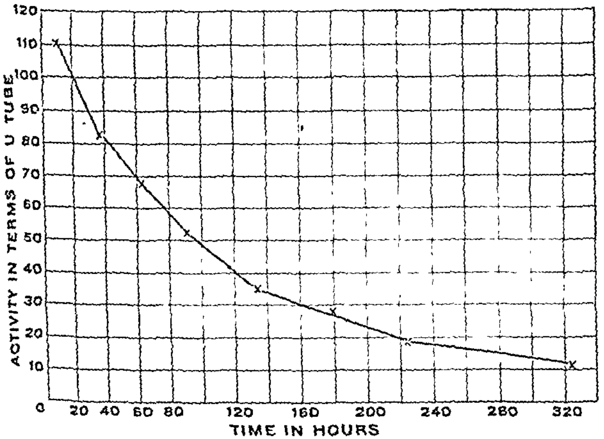

Fig. 3.—Curve showing the decay of activity of radioactive charcoal in sealed tubes.

MEASUREMENTS ON THE ACTIVITY OF COCOANUT CHARCOAL MADE ACTIVE BY ABSORBING RADIUM EMANATION

PREPARATION OF THE ACTIVE CHARCOAL

About 12 gm. of powdered charcoal were divided between two U-tubes, which were connected with each other and also with an aspirator.

One gram of radium chlorid of 1,000 activity was put in a test-tube. Through one of the holes of the two-holed stopper of this test-tube a thistle-tube was introduced which almost touched the bottom, while another glass tube made connections at the top with the U-tubes. A little water was put into the test-tube, just enough to dissolve the radium chlorid, and the aspirator was regulated so as to draw a very slow current of air through the solution (of the radium chlorid) and the U-tubes containing the charcoal. This was kept on for three hours.

The charcoal thus prepared was divided into twelve small tubes and the tubes were sealed. The tubes were opened one at a time at various intervals and their activity compared with the activity of a standard uranium oxid disc.[1] The measurements were made by means of a Dolezalek electrometer, the needle of which was kept charged to 98 to 105 volts, during different measurements, the voltage remaining constant during each particular measurement. The same difference of potential was also applied between the plates of the testing apparatus.

It was found by experiment that freshly prepared charcoal gives out emanation under ordinary conditions which, diffusing into the testing apparatus, greatly interfered with the accuracy of the measurements; for this reason the first two or three readings, often taken in less than two minutes, were regarded as more reliable.

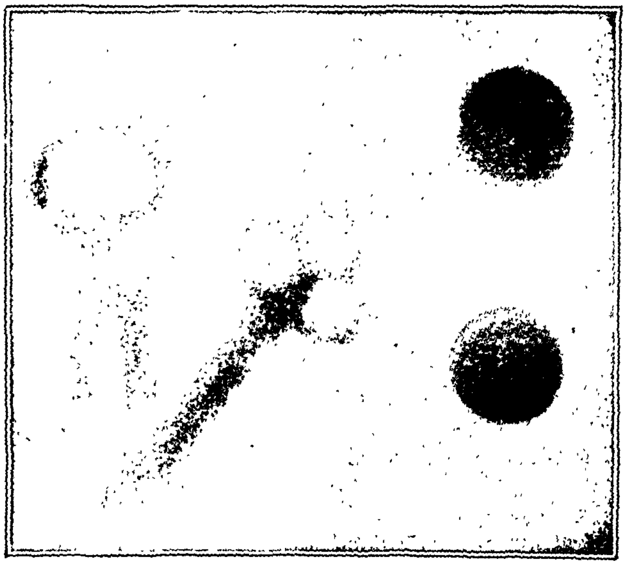

Fig. 4.—March 24 one-half of this plate was exposed to the action of about 1 gm of charcoal of about 10 activity, spread on a thin sheet of paper, while on the other part of the plate were placed six of the sealed tubes each containing 1 gm. of active charcoal. The difference in the shade of the negative clearly showed the results. The plate was exposed for ten hours; all the other plates were taken by means of the sealed tubes only.

To test the rate of diffusion of the emanation from such charcoal, kept in open vessels, samples were taken, having the same degree of activity with those in the sealed tubes and kept in an open test-tube, and the activity of this exposed specimen was measured under similar conditions. Also one of the samples was divided into two equal parts and one part kept in a sealed tube while the other was kept in a corked test-tube. The results of these measurements are given below:

(1) Wednesday, March 24.
Charge on the needle 98 volts.
Potential difference between the plates of the testing apparatus 98 volts.
12 hours after preparation.

ACTIVITY OF THE CHARCOAL IN THE OPEN TEST-TUBE IN TERMS OF U. DISC STANDARD

Specimen having an activity of 110, of U. disc.

24 hours after exposure, Activity = 11
48 hours after exposure, Activity = 7.8
72 hours after exposure, Activity = 6.6
7 days after exposure, Activity = 6.6
9 days after exposure, Activity = .9
13 days after exposure, Activity = .4

We see from the figures given that charcoal powder made radioactive by absorbing radium emanation when kept in sealed glass tubes loses its activity slowly, owing to the decay of the emanation absorbed. On examining the curve of decay of activity of such charcoal it is seen that the shape of the curve is not unlike that of the decay curve of the emanation itself. The fact that it reaches the half value in less than four days may probably be explained by supposing that the charcoal so enclosed (probably) gives out some of the emanation absorbed, which diffuses into the glass tube, thereby diminishing its activity. The figures given above show that if the charcoal is kept in an open test-tube instead of sealed tubes, the loss of activity is very rapid and falls to about one-tenth of its original value in twenty-four hours, if the powder is well exposed, (*i. e.*, when the depth of a layer of powder is not greater than the exposed surface).

In thirteen days the activity has fallen to about 2.36 per cent. of its original activity.

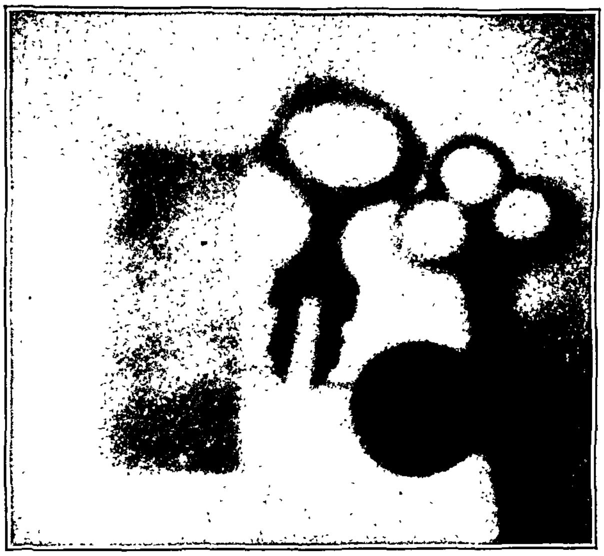

Fig. 5.—March 27. Objects exposed from 10 a. m. to 10 p. m. Exposure twelve hours.

One gram of charcoal of about 100 activity was divided into two equal parts and one was kept in a small corked test-tube while the other was in a sealed tube. Their activity was measured after fifteen days and the part in the sealed tube was found to be four times as active as that in the corked tube.

Several photographic tests were made to measure the activity and rate of decay of these sealed tubes, and of the charcoal itself. The results are seen in the illustrations, Figures 4 to 6. The objects seen on the negatives are one brass and one steel key, one cent piece and a piece of plate glass about 2 mm. in thickness.

Attention is called to the fact that the charcoal in the sealed tubes is radioactive at the end of sixteen days.

It will be seen from this report that by a very simple method and by the use of weak radium, cocoanut charcoal can be raised to a very high grade of radioactivity. Whereas water can be raised to only a fraction of the radioactivity of uranium oxid, which at the present time is taken as the unit of radioactivity, cocoanut charcoal, according to this report, can be raised to 110 times the radioactivity of uranium oxid. And, whereas water loses its radioactivity entirely in a few days, cocoanut charcoal retains a radioactivity above ten times that of uranium oxid for more than thirteen days. Subsequent experiments have shown that we can raise the charcoal to 160 times the radioactivity of uranium oxid.

In connection with this report it may be of interest to quote from an article[2] on "The Absorption of Radioactive Emanations by Charcoal," by R. W. Boyle, communicated by Prof. E. Rutherford:

> The experiments of Sir James Dewar in 1903 drew attention to the property possessed by the charcoal of cocoanut of absorbing gases in a remarkable degree. Since then this property has been investigated by several experimenters[3] and has been applied by Sir William Ramsay in separating the inert gases helium and neon from the air, and measuring the quantities in which they exist in the atmosphere. The results in the papers mentioned below may be summarized as follows:
>
> 1. The absorption of gases by cocoanut charcoal is greatly increased by lowering the temperature of the charcoal.
> 2. The charcoal has a greater affinity for some gases than for others, there being something of the nature of a selection absorption.
> 3. In consequence of this property, it is possible to separate from one another, in some degree, the constituents of a mixed gas. Of the inert gases of the argon family, argon is absorbed in about the same degree as ordinary gases, but helium and neon in a much less degree, and helium less than neon.
> 4. The absorption is also influenced by the pressure of the gas in contact with the charcoal, the pressure concentration curves varying in a regular manner with the temperature.

Fig. 6.—April 9. Objects exposed twenty hours.

Boyle then refers to Rutherford's letter to *Nature* above mentioned and states that he pointed out that this property of cocoanut charcoal also holds for the radioactive emanations. Experimenting with radium and thorium emanation, Boyle found that in the case of charcoal in granulated form the amount of absorption depends on (a) the nature of the charcoal, (b) the speed of the air-current through the absorbent, (c) the amount of charcoal surface exposed to the emanation, and (d) the temperature of the charcoal.

He concludes by stating that the percentage of absorption of thorium emanation by means of charcoal (1) depends on the nature of the charcoal used, being greatest for cocoanut charcoal, intermediate for animal, and least for wood charcoal; (2) is decreased by increasing the velocity of the gas-current which conducts the emanation through the charcoal; (3) is increased by increasing the charcoal absorbing surface, and (4) is dependent on the temperature, following the law of ordinary gases, viz., that a lowering of the temperature of the charcoal causes an increase and a raising of the temperature a decrease in the amount of absorption.

It takes about two or three hours to exhaust all the emanations from 1 gm. of 1,000 radioactive radium.[4] Before the radium can be utilized again the solution must be evaporated to dryness and the radium must be allowed to rest for about ten or fourteen days before it has recovered itself sufficiently to give off its full quota of emanation. The amount of charcoal which can be charged at any one time has not been accurately determined, but it will probably depend on the degree of radioactivity desired. I have been able to obtain on one charge sufficient charcoal of 140 activity to fill five small test-tubes, each containing enough to supply a patient for fourteen days, the dose being about as much as would cover a dime, taken three times a day. The tubes are stoppered with rubber corks and kept in a cool place, and the patients are instructed to replace the cork immediately after each dose. A fresh tube should be supplied about every ten days or two weeks. We have not found it necessary to prepare the charcoal either by cooling or heating. The current of air which carries the emanation into the charcoal is passed very slowly and in order that the gas may pass over as large a surface of the charcoal as possible it is placed in a glass tube eighteen inches long having a diameter of half an inch. After this tube is charged the charcoal is quickly transferred to small test-tubes, which are stoppered immediately with rubber corks. The charcoal in these tubes has an initial radioactivity of 120 to 160 times that of the uranium disc and remains strongly radioactive for two weeks.

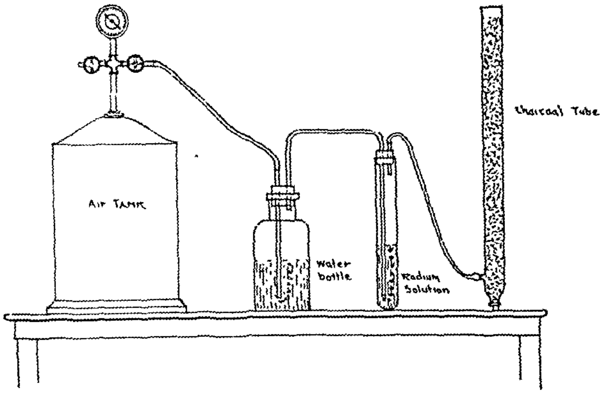

Fig. 7.—Author's method of charging cocoanut charcoal with radium emanation

I therefore feel that I have developed a very easy and simple method of utilizing radioactive emanations internally as well as externally, for there is no reason why the charcoal should not be incorporated in ointments or gelatin or other solutions and applied in cases of leg ulcer, lupus, eczemas and other cutaneous lesions. The effect of the internal administration of such charcoal on metabolism and its value as a therapeutic agent in many diseases will require careful study and accurate observations in many carefully selected cases before any definite conclusions can be drawn.

The *Archives of the Roentgen Ray* for January, 1909, contains an abstract of a paper[5] by Dr. F. Nagelschmidt, of the Finsenklinik, Berlin, on the "Therapeutic Action of Radium Emanation." Mention is made of previous work by Lowenthal and by Laqueur. Lowenthal administered preparations containing radium emanations, which he found useful in articular rheumatism and chronic neuritis, while Laqueur worked with tablets containing an emanation salt, and it is stated that neither of them observed any ill effects apart from the ordinary reaction. The reaction referred to is probably the erythema which might follow the local application of the preparations. The quantity of radium emanation in Laqueur's emanosal tablets is said to be very small. The internal therapeutic dose is from 10,000 to 20,000 emanation units per diem, gradually increasing. For the bath 100,000 to 200,000 emanation units are given, the patient remaining in the water for half an hour. If reaction sets in the treatment must be intermitted.

[4] The time for exhausting all the emanation stored in radium depends on the velocity of air-current and probably is much less than three hours.

[5] Nagelschmidt, F.: Berl. klin Wchnschr., March 16, 1908.

Nagelschmidt's preparation appears to be entirely different. An insoluble salt of radium is enclosed in a parchment capsule and placed in water, which, he asserts, is thus kept charged with the radium emanation. He uses this water internally and externally by compresses and baths. It is stated in the abstract that, like Lowenthal, he has had satisfactory results in cases of muscular and articular rheumatism, in neuritis, in ozena and in catarrh. He did not observe the bath reaction in articular rheumatism. His doses began with 2,000 units and were increased to 10,000. He believes that the emanation treatment may be counter-indicated in certain cases, and cites a case of latent ulcer of the stomach, in which profuse hematemesis came on after eight doses of the emanation. This observation may be taken in connection with the fact that wounds of patients taking the Gastein waters, which are markedly radioactive, heal with difficulty. Contrary to Lowenthal's observations, the presence of emanation was not found in the urine and feces of his patients. It is asserted that this treatment is indicated in diseases of the respiratory organs, in arteriosclerosis, in rheumatic, subacute and chronic diseases of the joints or nerve sheaths, the mucous membrane or the muscles, such as are treated at Wiesbaden or Baden-Baden, and that ozena, from whatever cause, is amenable to the emanation without any further treatment.

The class of cases in which I am inclined to test the value of this agent is that of chronic diseases which do not yield to our present methods of treatment, such as chronic gastritis or duodenal or intestinal ulcers, tuberculous ulceration of the intestine, various forms of functional diseases of the stomach or intestine, carcinoma of the stomach or esophagus, chronic muscular or articular rheumatism, neuritis, arteriosclerosis, certain general skin diseases, such as psoriasis and the eczemas, all forms of tuberculosis and in general debility after wasting diseases, in which the agent may be used as a tonic.

In addition to this, since the same rays are given off from the emanation as are obtained from radium itself we may find that the same therapeutic effects follow the local application of celluloid tubes filled with cocoanut charcoal in which the emanation is captured, as follow the local application of a tube or capsule containing radium. The potency of such a tube will, of course, diminish from day to day, but with improved methods will last long enough to allow of several treatments in a given case, when a new tube can be obtained from the source of supply.

In conclusion I beg to submit the following observations for the consideration of the medical profession:

1. Cocoanut charcoal is an inert substance and can be administered freely internally.
2. Cocoanut charcoal will absorb and retain the emanation of radium and, when treated by my method, can be raised to a very high degree of radioactivity compared to water—namely, from 200 to 300 times the radioactivity of the most radioactive water.
3. It can be prepared with but small expense. The same radium can be used over and over again indefinitely; none of the radium need be lost.
4. The charcoal will retain its radioactivity for at least two weeks and the method of administration is simple.
5. The beneficial effects of radioactive spring waters in many diseases and the results obtained abroad by the administration of weak emanation preparations warrants the belief that in this highly radioactive charcoal we have an agent the use of which will be followed by the same if not better results.
6. The local application of emanation cocoanut charcoal in tubes or capsules or incorporated in ointments or solutions is worthy of trial.

1731 Pine street.

Clinical Notes

ASEPTIC MITTENS

FRANKLIN BRADY, M.D.
Surgeon to Roosevelt Hospital
PHILADELPHIA

After scrubbing the hands and arms, preparatory to operative or obstetric work, it is important to keep them clean. Frequently, I have seen an operator or his assistant, or both, clean the hands and arms thoroughly, then, while waiting for the patient to be anesthetized, walk around the room with their hands by their sides, brushed by a passing nurse's apron or a physician's coat.

To overcome this difficulty, I introduced into my operating room, fifteen years ago, what I call "mittens," which are nothing more than bags of double thickness. These mittens are made of canton flannel and are in two sizes, short and long. When finished the short ones measure about 6 by 13 inches, the long ones 6 by 19 inches.

View showing the way the aseptic mittens protect the hands after sterilization.

They are made as follows: For the short mittens, cut two pieces, 14 by 14 inches, and fold them in the center so as to leave the fleecy sides out. Stitch across the end and up one side; this will make two bags 7 by 14 inches.

---

[6] The Journal A. M. A., Dec. 19, 1908, p. 2173.

One bag should now be turned fleecy side in and the other bag inserted into it, so that the fleecy sides are in contact. The raw edges are now turned in and the two bags stitched together, giving a bag of double thickness. To make the long mittens, two pieces 14 by 20 inches are cut and folded in the long axis and stitched as described above. The sizes I have given are those I find most convenient.

With a little practice one can, without soiling the hands, do a great deal with the mittens on: unpin packages of dressings, move tables or chairs; if necessary, assist in arranging the patient, etc. Care must be taken not to get the mittens damp, because the dampness, passing through the mitten, will carry microorganisms through to the hands.

The reason for making them of canton flannel is that it is thick, and dirt will not pass through as quickly as it would if made of muslin or other thin material. They are made of double thickness so that if by any means a little dirt should pass through the one thickness you are guarded by the second.

The short mittens are worn when it is important to have only the hands and the lower parts of the arms clean. It is always important to clean the arms above where the top of the mitten comes; otherwise the top edge would become soiled and in slipping it off and on would soil the hands. When ready to remove the mittens let them slide off the hands in such a way that if it is necessary to use them again they need not be picked up, but the hands simply thrust into them. Care should be taken to put them where the ends will not be brushed by those passing; otherwise the ends become soiled and soil the hands and arms as they are put on.

My method of sterilizing the mittens is the same as that employed in sterilizing towels. The short mittens are not folded, the long ones are folded once, they are wrapped in double thickness of unbleached muslin or cotton toweling and pinned, having a tag marked "short mittens" or "long mittens" as the case may be.

PROTEIN FEVER: THE PRODUCTION OF A CONTINUED FEVER BY REPEATED INJECTIONS OF PROTEIN

A PRELIMINARY NOTE

VICTOR C. VAUGHAN, M.D.
SYBIL MAY WHEELER, PH.D.
AND
WILLIAM F. GIDLEY, B.S.
ANN ARBOR, MICH.

The purpose of this paper is to make a short preliminary report on some experiments in which we are now engaged The work done in the hygienic laboratory of the University of Michigan during the past ten years in the study of the cleavage products of proteins, bacterial, vegetable and animal, has, in our opinion, given us quite a new point of view from which to study the infectious diseases. We have shown that all the true proteins which we have investigated, now more than thirty in kind and from diverse sources, may be split up into poisonous and non-poisonous proteins or into toxophors and haptophors. The toxophor group seems to be the same so far as its effects on animals are concerned, whatever the protein from which it is derived. Egg-white contains the same poison, physiologically at least, as that found in the typhoid bacillus, and if egg-white could grow and multiply in the animal body it would, as a result of such growth and subsequent cleavage, be just as deadly as the bacilli of the infectious disease. When a man drinks water containing typhoid bacilli and proves susceptible he does not immediately manifest symptoms of this disease. There is a period of incubation, which in typhoid fever is about ten days. During this time the bacilli are multiplying in the man's body in great numbers and still the man has no warning of their presence. Instead he often feels quite well during this period of incubation. We must, therefore, conclude that it is not the growth and multiplication of the bacilli directly that cause the disease. While growing and multiplying in the body the typhoid bacilli are converting the proteins of the man into bacterial proteins. They are converting normal and native proteins into abnormal and foreign proteins, and this process continues for about ten days before the man feels ill or the first symptoms of the disease develop. What new factor is it, then, that appears, closes the period of incubation and ushers in the disease? This new factor is the sensitization of the body to the foreign protein which has been introduced from without in the form of a few bacilli which have grown and multiplied by feeding on the proteins of the man's body. This sensitization consists in the development in certain cells, most probably connective tissue cells, of a specific proteolytic ferment which splits up the foreign proteins, existing as bacterial cells. It is a belated attempt on the part of the body to destroy the invader. The period of incubation is measured by the time necessary to develop this ferment, and it varies with the nature of the foreign protein and the species of animal invaded. We can not induce a continued fever in rabbits and guinea-pigs by inoculating them with the typhoid bacillus, because this protein sensitizes these animals within a few hours instead of a few days, and within a short time the animal is either dead or well. This is a condition like unto that which renders man immune to many bacteria. His cells are soon sensitized, and the invading organism is killed before it has time to multiply and store up enough poison to kill him. We have shown that it is the non-poisonous portion of the protein molecule or its haptophor that sensitizes the animal or leads to the development of the specific ferment. This is a brief statement of the conclusions which we have reached from our studies of the proteins and their cleavage products and their relation to the infectious diseases. We are quite aware of the fact that our views have not met general acceptance, and consequently we are glad to present herewith what we believe to be a marked confirmation of our teachings.

It occurred to us that if the above given ideas be correct we should be able to induce in animals a continued fever by repeated subcutaneous injections of a soluble foreign protein. We have done this with bacterial proteins, but, since vitalistic dogmas cling so closely, we intend to present herewith an illustration of the results that we have obtained by repeated subcutaneous injections of egg-white dilutions in rabbits. The whites of fresh eggs have been diluted with an equal volume of 0.5 per cent. phenol solution.

Table 1 is self-explanatory, and the record is strikingly similar to one for typhoid fever. We have here a condition practically identical with an infectious fever and yet without any infection. Fever results when any foreign protein finds its way into the blood and the body becomes sensitized to it and begins to split it up. The foreign protein may be from the animal's own body. The subcutaneous injection of solutions of silver nitrate or other destructive chemical agents causes fever by de-

§ Died at 7:05.

stroying the tissue with which it comes in contact. An injury that crushes and destroys tissue without breaking the skin or being accompanied by bacterial infection causes fever because the broken-down tissue is absorbed into the circulation. Fever, more or less marked, accompanies perfectly aseptic operations in which tissue is destroyed and left in the body. In the intermittent fevers the elevation of temperature is simultaneous with or immediately subsequent to the discharge of protein into the blood. In the infectious diseases the primary, multiplying, invading cell supplies and maintains the foreign protein. In our experiments we have kept up the supply of foreign protein by the frequency of our injections.

There are certain things in Table 1 to which we may call attention. The loss in weight is gradual, with some slight fluctuations; it continued for some six days after the injections were discontinued, after which it gradually increased. The amount of urine is quite variable, but averages much less than normal, as it does in typhoid fever in man. The elimination of nitrogen is increased as it is in the fevers to which man is susceptible. The temperature of the fore period varied from 101.8 to 102.5. The first injection of egg-white was made at 1 p. m. May 27. During the next twenty-four hours the temperature kept below the normal average. It is noticeable that when the dose was increased from 2 c.c. to 4 c.c. there was a marked rise at the end of twenty-two hours. When this dose was again doubled, no marked effect on the temperature was seen until the next day. If one will follow down one of the morning hours he will see the gradual rise in the morning temperature so generally observed in the development of typhoid fever. Equally

TABLE 4.—THIS RABBIT RECEIVED SUBCUTANEOUSLY 200 MG. TYPHOID TOXIN (FILTERED, NEUTRALIZED, REFILTERED) EVERY 2 HOURS, BEGINNING 5/4/09. URINE AND WEIGHT TAKEN AT 1 P. M. 117 DOSES GIVEN IN 15 DAYS (23.4 GM. TYPHOID TOXIN)

* Urine normal in amount for 22 hours.
D = Dose.

striking is the fact that for the most part the highest temperature for the day falls in the afternoon. When the injections were discontinued the temperature gradually fell and remained somewhat below the normal, as is often observed in typhoid.

We were anxious to determine the nature of the albumin in the urine—whether it was some of the egg-albumin injected or came from the serum albumin of the animal's blood. In order to determine this we injected 2 c.c. of the filtered urine of June 18 intra-abdominally into each of five guinea-pigs for the purpose of sensitizing them to whatever proteins the urine might contain.

Twelve days later two of the pigs received intra-abdominally each 5 c.c. of egg-white dilution (with an equal volume of water); two others had each 5 c.c. of fresh serum from a rabbit, and the fifth had a mixture of 2.5 c.c. of each of these fluids. All the animals were found to be sensitized, thus showing the presence of both egg-white and serum protein in the urine of the febrile rabbit. It is worthy of note that, while these animals developed the three stages characteristic of protein sensitization, the second and third stages were unusually prolonged and less acute than those generally observed in sensitized guinea-pigs. Of the two treated with egg-white, one died at the end of two hours and the other fifteen minutes later. Of the two treated with rabbit serum one died at the end of one hour, while the other lived for three hours. The one that had the mixture of proteins developed the symptoms more promptly than any of the others, but did not die.

If less than a fatal dose of the poisonous group of a protein be injected into an animal, recovery is speedy and at the end of two hours the same dose may be repeated.

The effect of a single dose is to lower the temperature, but when repeated doses are employed a continued fever develops. Within a few days, however, the time depending on the size and frequency of the dose, the animal dies. The effects of the free, unneutralized poison are shown in Tables 2 and 3. In these the poisonous portion of the protein of the typhoid bacillus was used.

The fact that an animal recovers so speedily from only a little less than a fatal dose of the protein poison shows that this poison must be quickly neutralized in the animal body. We are inclined to the opinion that this neutralization is secured only by the destruction of the tissue of the animal body.

It was shown by V. C. Vaughan, Jr., some years ago, that the neutralization of the poisonous group of the protein molecule greatly reduces its toxicity. This led us to try repeated subcutaneous injections of the poisonous group from the typhoid protein after neutralizing it with sodium bicarbonate. The results of these injections are shown in Tables 4 and 5:

We think that these investigations show that fever results when a foreign protein is introduced into the blood. This foreign protein is not necessarily of bacterial origin, though under natural conditions this is usually the case in continued fevers. The fever results from the cleavage of the foreign protein and from the effect of its split products on the body tissue. The object that Nature seeks to accomplish in this process is the destruction of the foreign protein. The effect of the high temperature *per se* on the infected animal is slight. The ill effects, the wasting of tissue and death in which fever often results are due to the action of the protein poisons that are set free.

UNDIAGNOSTICATED BRAIN ABSCESS

F. DOWNING, M.D.
BALTIMORE

In THE JOURNAL of May 22, 1909, Dr. Eshner reported a case of undiagnosticated brain abscess. In a day when chiefly successes are given to the medical press I feel like congratulating the Doctor for his courage in publishing a failure, for as such much be regarded all cases which are undiagnosticated, or are wrongly diagnosticated.

Though it is embarrassing to report mistakes, the science of medicine is often materially promoted thereby and the fear of criticism arising from a pardonable failure of diagnosis should not prevent one from speaking of the undiagnosticated. For that reason a parallel case to Dr. Eshner's is submitted.

History.—X., male, aged 27, was admitted to St. Joseph's Hospital May 3, 1909, complaining of severe headache. There was nothing of note in his previous history except that he had had an otitis media in early life which gave him very little trouble. General health had always been good; no history of venereal infection of any kind. For the past two years he had been somewhat out of sorts, not positively sick, but not feeling quite himself. Occasionally during the past six months he complained of pain in the left ear. About March 10, 1909, he was taken with what was thought to be influenza and was sick about two weeks, during which he had an attack of unconsciousness lasting a few minutes. In the first week of April he again became sick with what was said to be "typhoid-pneumonia" and was under treatment in another hospital for three weeks. He left feeling rather weak but otherwise apparently well. About one week later he began to suffer pain in the head, and had another spell of unconsciousness which came on suddenly and lasted only a few minutes. No convulsions were noticed by the family and no paralysis observed after the attack. Two or three days later he had a third attack of unconsciousness. During the night of May 2 he suffered intensely with headache and was taken to St. Joseph's Hospital the following day complaining of great pain in the head, especially on the left side.

Examination.—Patient fairly well nourished; complexion sallow; tongue coated; breath fetid; appetite good; no rigidity of muscles of neck; no vomiting; no vertigo; but rather obstinate constipation. Abdomen negative; few scattered râles and dulness at base of both lungs posteriorly. Expectoration contained a few diplococci but no tubercle bacilli. Heart negative; pulse 60; temperature 98.4 F.; respiration, 20.

Urine: cloudy, alkaline, specific gravity 1,025, no albumin, slight amount of sugar; under microscope, few epithelial cells and triple phosphates.

Blood: Leucocytes, 18,200; differential couunts, polymorphonuclear, 81; large mononuclear, 4; small mononuclear, 10; eosinophiles, 1; basophiles, 1; myelocytes, 3; number of cells counted, 337.

Eyes: Direct and consensual reflexes present but not so active as normal; surface of each disk raised, grayish-white, edges blurred and "fuzzy," veins enlarged and tortuous; no hemorrhages and no exudates in retina. Choked disk was somewhat more marked on left side. Central vision was good; there was no paralysis of the external ocular muscles and there was no nystagmus.

Ears: Right side showed evidence of previous otitis media which had fully healed with no impairment of hearing. On left side were a partly defective drum, little moisture in tympanum with faint odor, and slight impairment of hearing. No fistula, no sinking of posterior-superior wall, no tenderness about mastoid or along sigmoid groove or over the occipital protuberance.

Slight loss of power was observed in right hand and some little dragging of right foot. Patella reflex exaggerated at first on both sides, but absent after a few days in hospital; ankle clonus present on admission but absent one week later. Kernig sign present on both sides; Babinski sign present, also *tâche cérébrale*; areas of anesthesia over portions of right foot; no aphasia. Mental condition good; answered questions intelligently; was rather anxious about outcome of his illness.

Hospital History.—During his illness in the hospital the patient's chief complaint was headache. He vomited only once, had no chills, and never complained of vertigo. Potassium iodid had no effect. Two lumbar punctures drew no fluid whatever, though needle was clearly in spinal canal. Edema of optic nerve head increased only slightly, never became great, and examination of eye grounds three days before death showed no retinal hemorrhages. Central vision remained good up to two days before death. Temperature ranged from 96.4 F. to 100.5 F.; pulse from 60 to 110; respiration 16 to 24. For twelve days before death he would have several hours of coma alternating with periods of consciousness. The latter gradually becoming shorter, the periods of coma longer until 24 hours before dissolution, when deep coma set in. Death occurred May 25, 1909, on the twenty-second day of his residence in hospital.

Autopsy.—Brain with enveloping dura came out easily. There was no pus on outer or inner surfaces of dura. Vessels of pia on left hemisphere congested. There was discoloration with slight bulging of the cortex high up on left parietal lobe extending to the longitudinal fissure. Incision into this fluctuating area released from 6 to 8 ounces of foul-smelling pus. Abscess cavity involved the greater part of the parietal lobe and extended well down into the temperosphenoidal. The cortical wall of the abscess lay just posterior to the fissure of Rolando. No pus in any of the ventricles. Decided softness of brain tissue surrounding abscess cavity. Roof of petrous portion of temporal bone was found intact. No communicating channel between middle ear and abscess was made out. Mastoid and cerebral sinuses unfortunately were not opened. General section was not permitted.

The staff was divided in regard to diagnosis. Internists were for meningitis until this was negatived by lumbar puncture, the neurologist was for inoperable brain tumor, the otologist for brain abscess. In deference to the greater experience of the neurologist in intracranial affections, diagnosis of tumor prevailed. Headache, constipation, slight motor and sensory involvement on the right side and double choked disc were the chief symptoms. Abscess had probably existed for some time, patient's illness of March and April being due to this and not other causes. Although no direct route of suppuration was made out between middle ear and cerebral abscess, it is highly probable that the abscess was of otitic origin, infection occurring, if not by direct extension, by metastasis.

INGUINAL HERNIA OF THE BLADDER

H. E. RANDALL, M.D.
FLINT, MICH

Hernia of the bladder through the inguinal canal, while rare, is a condition that must be borne in mind when operating on any hernia, either femoral or inguinal. Failure to recognize this rarity has led to disastrous results. Cooley, in Keen's "System of Surgery," says that but three cases of hernia of the bladder were encountered in a series of over 1,900 cases of hernia in patients operated on at the Hospital for Ruptured and Crippled.

History.—Miss H., aged 20, first noticed a small bunch in the right inguinal region last April. This did not disappear and was painful at times, but she continued teaching school. The mass felt like a fatty growth. At times it was thought that an impulse on coughing could be felt and at other examinations no impulse on coughing could be detected. There were no bladder symptoms. Symptoms were similar to that of an enlarged tender gland.

Operation.—This was performed at Hurley Hospital, July 13, 1909. On cutting down to the mass it looked and felt like a lipoma except that the walls could be moved on each other as though there were a cavity in its center. The mass extended down into the inguinal canal. After separating the mass from the adhering structures it appeared as a diverticulum of the bowels. A sound passed into the bladder easily passed into this diverticulum, making the diagnosis of an extraperitoneal direct inguinal hernia of the bladder. The bladder was returned to the abdominal cavity and the abdominal wall closed with silk-worm gut sutures, with layer suturing with catgut.

The case of Justo is interesting because, after making a diagnosis of vesical hernia from the patient's symptoms, he cut into the fatty mass and opened the bladder because he was unable to distend this portion of the bladder by fluid, concluding that no vesical hernia existed.

New and Nonofficial Remedies

SINCE THE PUBLICATION OF THE BOOK "NEW AND NONOFFICIAL REMEDIES, 1909," THE FOLLOWING ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK ARE ASKED FOR.

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

(Continued from page 530)

IODONE SURGICAL DRESSING AND DUSTING POWDER—Pulvis Iodoni Compositus.—Iodone surgical dressing and dusting powder consists of four parts of iodone $((C_6H_4C_2O_3)_2KI.I_4)$, a periodide of phthalic acid anhydride and 96 parts pure sterile talcum.

Iodone is prepared by treating a solution of phthalic-acid anhydride in acetic ether, with a solution of iodine and potassium iodide, and crystallizing the product from suitable solvents.

Iodone occurs in the form of dark green prismatic crystals which melt with decomposition at 163° C. (325.4° F.). When freshly prepared it is odorless, but on standing, traces of iodone are liberated, giving it a faint odor of iodine. It is gradually decomposed into phthalic acid, iodine, and potassium iodide by water, in which the decomposition products dissolve until a saturated iodine potassium iodide solution results. Any excess of iodine remaining in contact with the supernatant liquid remains unchanged. Alcohol, chloroform, and ether decompose iodone, but more slowly than water. Iodone crystals are stable in dry air; exposed to damp air, they gradually liberate iodine.

When 0.1 Gm. iodone is heated in a crucible at not more than a dull red heat, the compound chars, iodine vapor is driven off, and a residue of white potassium iodide remains. At a bright red heat, the latter is dissipated, leaving no weighable residue (absence of metallic impurities).

About 0.1 Gm. iodone, accurately weighed, is allowed to react, with occasional agitation, with a solution of 1 Gm. potassium iodide in 50 c.c. water. At the end of 15-20 minutes the titration of this solution with tenth normal thiosulphate solution should indicate the presence of not less than 51.1 per cent. iodine.

Iodone surgical dressing and dusting powder, assayed by the above process, should yield not less than 2 per cent. of available iodine. (About 2.5 Gm. should be taken for the assay.)

Actions and Uses.—Like iodine, iodone is a potent germicide and stimulant to the processes of repair in wounds. It is said to be useful in all conditions in which the local use of iodine is indicated, also as an antiseptic dressing in wounds and all local affections.

Dosage.—Its employment as a surgical dressing and dusting powder should be regulated on the basis of its containing 2 per cent. of available iodine, slowly liberated on contact with the moisture of wound secretions, etc.

Manufactured by The Henry C. Blair Co., 800 Walnut St., Philadelphia, Pa.
U. S. patents applied for.

PEPTONE—Peptonum.—Peptonum (Pharm. Belgica., edit. 3); Peptona Medicinalia (Pharm. Francaise, 1908).

Peptone is a product of the peptic or pancreatic digestion of albuminoid substances.

Peptone may be produced artificially as follows: Mince 1000 parts of lean beef freed from bone, etc., and mix it with 4000 parts of water, to this add a solution of 5 parts of pepsin in 1000 parts of water with 50 or 25 parts of hydrochloric acid. The mixture thus prepared is kept at a temperature not exceeding 50° C. (122° F.) until 10 Cc. of the filtrate or the addition of 1.5 Cc. of nitric acid in the cold no longer produces a precipitate. (Formation of a coagulum indicates incomplete peptonization.) The solution is then filtered, neutralized with sodium bicarbonate and evaporated to dryness in vacuo. It may be purified if necessary from adherent sodium chloride by dialysis or by precipitation by alcohol washing with ether and drying. By desiccating its concentrated solution upon plates peptone may be obtained in scales. (Brit. Codex.)

Peptone occurs as a white or yellowish-brown amorphous powder or in scales, with a somewhat cheesy but not unpleasant taste and nearly odorless. The pure substances when added to water hisses and froths at the same time evolving heat. It is soluble in water (1 in 20) forming a neutral solution or slightly acid. Aqueous solutions are pale yellow and clear or may be made quite clear by the addition of a little hydrochloric acid. The addition of alcohol precipitates peptone. Aqueous solutions are not coagulated by heat. No precipitate is formed in aqueous solution on the addition of nitric acid or potassium ferrocyanide (difference from albumen) nor is a precipitate formed by solutions of ferric chloride or cupric sulphate nor by saturation with ammonium sulphate or zinc sulphate (distinction from albumoses). The aqueous solutions are laevorotatory. Neutral solutions are precipitated by tannin and by various salts of mercury. Acid solutions give precipitates with bismuth potassium iodide, potassium mercuric iodide, bromine water and other precipitants of alkaloids. Peptone is colored yellow with Millon's reagent on warming a red color and precipitate; with cupric sulphate and caustic alkali a violet red color (biuret reaction). Picric acid gives yellow flakes. Peptone should not be precipitated by lead acetate, alum or hydrogen sulphide. On ignition it should not yield more than 2 per cent. ash.

Action and Uses.—Peptone is given as a nutrient in malnutrition and certain forms of dyspepsia. Its value is limited because larger amounts, often even small quantities, cause irritation.

Dosage.—Peptone is given in the form of pastilles, 5 Gm. in each prepared with gelatine. It is administered in rectal alimentation in the form of suppositories or it may be added to rectal enemata.

(*To be continued*)

Therapeutics

ECZEMA

This troublesome condition is often so difficult to cure that the thoughtful consideration of its treatment by Dr. E. G. Little (*British Medical Journal,* June 5, 1909) is well worth describing.

He makes the very pertinent dictum that it is the patient who has the eczema who is being treated, and not merely the eruption on the skin, and therefore believes it necessary that the patient should be subjected to a very careful physical examination. Also, the urine should be carefully analyzed, the diet should be investigated, and, in fact, no examination is too rigid to thoroughly understand the physiologic (or pathologic) condition of a patient who is suffering from eczema.

Little adopts Tilbury Fox's long descriptive definition of the disease, which it is well to bear in mind, viz.: "Eczema is a catarrhal inflammation of the skin which is mainly characterized by a peculiar discharge, stiffening linen and drying in thin yellow crusts, and having its stages of erythema, papulation, vesiculation, discharge, pus formation, and squamation more or less marked under different circumstances and followed in some cases by the secondary results of inflammation such as hypertrophy, edema and the like."

ACUTE ECZEMA

This is an erythematous eruption, occurring mostly on exposed surfaces of the body and due to cold or irritants. This eruption may abort at this stage, or it may go on to vesication, exudates, and even pus infection. The disease is not contagious.

The best treatment of this condition is rest in bed, with a low diet and the use of sedative lotions. Little believes that a pure milk diet is the best. The bowels should be kept loose, best with saline laxatives; it is unimportant which one is selected—Rochelle salt, effervescing phosphate of soda, or artificial Carlsbad salts, a teaspoonful or more (enough for one or two movements of the bowels), taken in a glass of hot water before breakfast.

Little finds the best lotion for the skin to be similar to the following:

℞.	gm. or c.c.		
Acidi salicyli	10	or	ʒiiss
Liquoris plumbi subacetatis	150		fl. ℥v

M. et Sig.: Add one tablespoonful to half a pint of milk, and apply to the inflamed skin every four hours.

[Prepare fresh daily, and shake before using.]

CHRONIC ECZEMA

Little urges the necessity for very carefully investigating the patient's work and the possible use of irritants on the parts affected with the chronic eczema, before attempting to treat the disease. In many patients an irritant cause will be found, which if removed, or corrected, will allow the skin to become rapidly healed. If, in the work of the individual, there is a necessity for coming in constant contact with the irritant that has caused the trouble, the cure will be retarded and perhaps prevented. Whether the cause of the eczema be found or not, strong antiseptics or irritants should never be used in the treatment of the condition. If the skin is moist or weeping or red and itching, Little finds that lotions are more sedative than ointments. He suggests the following:

℞.	gm. or c.c.		
Calaminæ præparatæ	2		gr. xl
Zinci oxidi	1	or	gr. xx
Aquæ calcis	10		fl. ʒiii
Olei olivæ	25		fl. ℥i

M. et Sig.: Apply with a brush or cotton swab.

This lotion may also be well applied by moistening gauze in the solution, placing it over the diseased skin, and holding it in place with thin bandages. The skin should never be heated with over-bandaging or thick coverings.

If the eczema has become purulent, the part affected should be subjected for twenty minutes to the action of a mild antiseptic solution, and perhaps the official Liquor Antisepticus will be of sufficient strength. It may, however, be necessary to use a bichlorid of mercury solution (1 to 3,000), or perhaps for a shorter period (ten minutes) one-half of a 1 per cent. solution of the official Liquor Formaldehydi, in water. The infected areas having been thus sterilized, the above soothing lotions may be applied.

When the oozing from the surface has about ceased and the skin shows a tendency to become dry, Little applies a paste in place of the lotion, and he believes Lassar's paste, or something similar, to be the best. The ingredients of this paste or ointment vary, but Little particularizes the composition as follows:

℞.	gm. or c.c.		
Acidi salicyli	2		gr. xxv
Zinci oxidi	25	or	
Amyli	25		āā, ℥i
Paraffin mollis	50		℥ii

M. et Sig.: Use externally.

If the skin shows considerable redness and irritation, the salicylic acid may be omitted, or the following ointment may be used:

℞.	gm. or c.c.	
Zinci oxidi	25	℥i
Aquæ calcis	25	or
Olei olivæ	25	āā, fl.℥i
Adipis lanæ hydrosi	10	ʒiii

M. et Sig.: Use externally.

This ointment having been spread thickly over the affected areas, a fine powder, as starch, may be dusted over the ointment so that it almost makes a dry dressing; no bandages are needed.

When the patient is first seen during the stage when dry crusts have formed and scabs from epithelial débris are present, local applications are useless until these are removed. To remove these scabs, wet dressings may be used, well applied by soaking clean, sterile gauze in warm boric acid solutions and applying it to the region of the crusts and scabs. These moist applications are then covered with an oil silk or rubber tissue and kept in place with a bandage. These dressings should be changed as often as they become dry. If pus organisms are present, the skin must be made sterile with one of the antiseptics, and when clean of crusts the above lotion or paste may be applied.

If chronic pus infection is present and the disease is not readily controlled by this treatment, vaccine therapy should be used.

If patches of inveterate eczema have persisted months or even years, associated disease or persistent causes should be suspected. These may be "ichthyosis, varicose veins, gout, diabetes, or tuberculosis." If any of these conditions are found, they should be properly treated, and with their improvement the skin condition will generally improve. A healthy exfoliation of the thickened epidermis may be aided by applying every four or five days the following lotion:

℞.	gm. or c.c.	
Phenolis liquefacti	15	or
Liquoris picis alkalini (N. F.)	15	
Glycerini	15	
Alcoholis	15	āā, fl.℥ss

M. et Sig.: Paint on the part with a brush, or swab, once in four or five days.

Each day during the interval the diseased surface should be dressed with some soothing lotion or ointment.

If the above phenol solution is too painful, the sensation of the parts may be first dulled with a cocain application.

In chronic eczematous patches occurring about the junction of the skin and mucous membranes, as the lips, vulva, anus, and on the nipple, nitrate of silver applications may be substituted for the above phenol combination. The fissure, or irritated, or inflamed part may be touched lightly with a swab wet with a nitrate of silver solution (15 to 25 per cent.). This may be done at intervals of four or five days, for several times, if necessary. However, prolonged nitrate of silver applications are inadvisable, as they may tend to prevent healing, and perhaps even give sufficient irritation, in older people at least, to cause pathologic growths.

Little has found picric acid in from 0.5 to 1 per cent. solution, in water, valuable as an application for itching in pruritus ani with fissures, and for itching of other excoriated surfaces.

Eczematous patches or fissures about the nipple occurring during lactation are often cured by one or two nitrate of silver applications, great care as to cleanliness after nursing, and by the continuous applications of saturated boric acid solutions.

In very chronic dry eczema Little obtains satisfactory results by applying gauze saturated with tarry preparations, and then covering the gauze with oil silk and bandaging for twenty-four hours. This same treatment may be several times repeated, if necessary. The Unguentum Picis Compositum of the National Formulary would be a suitable preparation for such use.

ECZEMA OF CHILDREN

The most frequent cause of infantile eczema seems to be exposure to cold, and such local irritants as hard water, strong soap, dirt and irritation caused by lack of cleanliness and neglect. The treatment is to treat properly any parasitic disease that may be present, to keep the parts that are subject to moisture scrupulously clean, to prevent the use of any irritant on the child's skin that could perpetuate the disease, to keep the part comfortably warm but not overheated, and to prevent scratching by any method that seems best. A simple strawboard splint on the arms, long enough to prevent flexion at the elbows, is generally sufficient to prevent scratching. The above calamine lotion and Lassar's paste will aid in curing the condition, but at times the disease in infants is difficult to cure.

Overfeeding and underfeeding should be prevented. The bowels should be carefully watched, both to prevent constipation and to see that the food is satisfactorily digested, and agrees with the child. It is sometimes advisable to cause the bowels temporarily to be rather loose. While the excessive use of artificial foods is often a cause of eczema in young children, still it occurs when the child is breast fed. Certainly, it is inadvisable to allow a restricted diet of artificial food that contains large amounts of salts. Large amounts of alkalies are certainly contraindicated, and the same is true of much acids. Water should be freely given. Change of air to the country or the seashore seems often advisable. This is especially true during the heated term, and overheating houses in winter, causing the child to become very warm, will prolong the disease.

Little does not believe that warm bathing of the eczematous child is inadvisable, and believes that the part may be bathed at any stage, with the precaution to use no strong alkaline or irritating soap, and to use either soft water or water that has been made soft by the addition of soothing powders. The inflamed area should never be rubbed, but should be dried by mopping with soft towels or gauze.

If there is much swelling or infiltration of the skin in children, Little administers calcium lactate, doubtless on the presumption that calcium prevents or inhibits exudation. As soon as the edema is less, he stops the administration of the drug. It may be given as follows:

℞.	gm. or c.c.		
Calcii lactatis	3	or	gr. xl
Aquæ cinnamomi	100		fl.℥iii

M. et Sig.: Two teaspoonfuls, in water, three times a day, before meals.

Nothing will hasten the improvement of these little patients more than fresh air, quiet, rest, and the prevention of mental as well as physical irritations.

Chinese Surgery.—Medical missionaries in China say that the natives will bear without flinching a degree of pain from which the stoutest of us would shrink in terror. A woman in Shao-wu, afflicted with a ulcer of the leg, was treated by a native "doctor." One day he came to the mission hospital to show the physician in charge a "string" which he calmly announced he had pulled from the wound. It was the sciatic nerve! To people suffering from such barbarous methods, and to whom anesthetics are unknown, the merciful methods of foreign doctors in the mission hospitals seem like miracles.

THE BACTERIOLYTIC ACTION OF BILE ON THE PNEUMOCOCCUS

Jaundice in pneumonia has generally been considered a very unfavorable prognostic sign indicative of an extreme grade of toxemia produced by the pneumococcus. If this explanation is true, the phenomenon first described by Neufeld[1] in 1900 of the lytic action of bile on the pneumococcus stands in almost paradoxical contrast. If one drop of fresh rabbit's bile is added to 20 drops of a broth culture of pneumococci in a test tube, there is almost immediate clearing up of the cloudy fluid, due, as is observed in a hanging drop under the microscope, to complete lysis of the bacteria. Bile salts were later found to act in the same way. The reaction is specific, as no other organism is dissolved by bile, and it has been of considerable importance in differentiating streptococci from pneumococci. The so-called *Streptococcus mucosus capsulatus,* which in most respects behaves like a variety of pneumococcus, is dissolved by even less bile than is required for the pneumococcus.

Recently Grixoni[2] has reported from Grocco's clinic a series of most interesting experiments conducted both *in vitro* and *in vivo.* All strains of streptococci tested gave negative results. Using six different strains of pneumococci he showed that the reaction depends largely on the bile used, as is to be expected from the varying chemical composition of "normal" bile at different times. Rabbit bile is more active than ox bile, and fresh sterile bile acts more rapidly than contaminated bile. The lytic power is lost at room temperature or at 37° C., and is damaged by heat of sterilization, but is retained if the bile is kept on ice. Both sodium glycocholate and taurocholate have lytic power, the latter acting more powerfully; but the dissolving power of the combined salts, each in 2 per cent. solution, is less than that of fresh bile, although greater than that of bile heated to 120° C. for an hour.

Neufeld[3] a short time before the publication of Grixoni's results confirmed his original observations, and showed that a direct relation exists between virulence and rapidity of lysis by bile. Grixoni independently reached the same conclusion, and found that a culture freshly isolated from the blood of an infected animal is dissolved in about one-fourth the time necessary for the same organism after it has grown on artificial culture media. Grixoni's animal experiments almost shatter any dreams of a practical therapeutic application of this reaction, at least in systemic pneumococcus infections like pneumonia. Subcutaneous, intraperitoneal and intrapleural injections of bile, or bile salts, protect only when given at the same place and time as the bacterial injection, so that what practically occurs in the experiments is an injection of organisms already dissolved. Given in any way, bile has no prophylactic power, while intravenous doses hasten the death of the animal, probably on account of the toxic action of the bile itself.

Remarkable as is the phenomenon of lysis by bile, no explanation of its cause has yet been offered. Neufeld suggests the possibility of its being related in some way to the capsules of the pneumococcus, but as no other encapsulated organisms yield the reaction no definite conclusions are to be drawn. At present it is a phenomenon *sui generis,* of importance in the differential diagnosis between pneumococci and streptococci and in testing the virulence of pneumococci.

THE PURIFICATION OF WATER BY OZONE

Ozone has been called the ideal agent of purification since it is only a more active form of ordinary oxygen, already existing normally in the atmosphere in small quantities, and since its application to water leaves behind no foreign chemical residue. The first attempt (1889) to sterilize water with ozone was reported by Fröhlich,[1] and was carried out with an apparatus manufactured by Siemens and Halske of Berlin. The Siemens and Halske method was installed later on a larger scale at Wiesbaden and Paderborn in Germany, and is said by Erlwein[2] to have given highly satisfactory results at those places. Other forms of ozonizing apparatus have been devised by Tindal (since improved by De Frise), Marmier and Abraham, Vosmaer and Otto, and are in use in several installations in Holland, France and Germany. The process has been investigated by a number of competent bacteriologists, including van Ermengem, Roux and others, and has shown in practically all cases excellent results. Bacteria in the water, including *B. coli,* are destroyed to such an extent that an initial content of 2,000-4,000 per c.c. is reduced to 1 or 2 per c.c. or even less. There is consequently no doubt as to the bacterial efficiency of the process.

The nature of a water treated by an ozonizing system is of some importance since it is plainly extravagant to employ ozone for the oxidation of any large quantity of chemical impurity. The method, for example, is hardly applicable to the direct treatment of a turbid river water containing a considerable quantity of organic matter in solution or suspension. At the St. Maur municipal waterworks of the city of Paris, where the DeFrise ozonization method is employed with considerable success for furnishing a portion of the Paris drinking water supply, the water of the river Marne is subjected to a preliminary clarification before it is ozonized. The river Marne is highly polluted with sewage, but after the water is passed through beds of sand and gravel and then treated with ozone it possesses a degree of bacterial purity indicated by the fact that *B. coli* is not found when quantities as large as 200 c.c. are tested.[3]

---

[1] Electrotechn. Ztschr., 1891, p. 344.

[2] Ber. über d. XIV Internat. Kong. f. Hyg. u. Demog., 1908, 3, p. 195.

The question of the relative expense of ozonization of large public water supplies as compared with that of sand filtration or of certain forms of mechanical filtration is a point on which it is not easy to secure definite information based on data covering a considerable period. Erlwein estimates that with a large plant the cost might be as low as about one-half cent per 1,000 gallons, and Rideal gives about two-thirds of a cent per 1,000 gallons as the actual cost of ozonization at St. Maur. Neither of these estimates includes the cost of preliminary treatment of a polluted water. In the absence of any uniform system of waterworks accounting, it is very difficult to obtain trustworthy information concerning cost of installation and operation of purification systems, though this is a vital point.

To justify the introduction of any new system of water purification, even though it be one of recognized efficiency, the question of comparative cost should be presented in such a way as to convince reasonable inquirers. This has not yet been done with the ozonization process.

THE FIRST PHYSICIAN

The first physician of whom we have any definite record is evidently I-em-Hetep, who lived in the reign of King Tchser, a monarch of the Third Dynasty of Egypt, the date of whose reign is somewhat uncertain, but is probably not later than 4500 B. C. In the light of recently awakened interest in psychotherapeutics and the use of the mind to influence the body, it is extremely interesting to note that his name, I-em-Hetep, means "the bringer of peace." According to tradition, he had two other titles, one of which was "The Master of Secrets" and the other "The Scribe of Numbers." The reference embodied in the first of these titles is easy to understand. The second is less easy of comprehension. Perhaps the writing of his prescriptions required an unusual knowledge of numbers in those days, for even at that time the Egyptians had a great many remedies that they employed for diseases of various kinds and many methods of administering them. He seems to have been held in high honor by his generation and to have received ample rewards for his professional work, for the well-known "step pyramid" at Sakkara, the old cemetery near Memphis, is attributed to him, showing that he was only next to the king in honor and also very probably in revenue.

Even more interesting than this, however, is the honor that was paid to him after death. Men had learned to trust him so much, they had come to realize how thoroughly he fulfilled his name, the "bringer of peace," and how often he had helped them in suffering, that after his death they concluded that he must have had more than human knowledge and so they made a deity of him and worshipped him. While doing this they were careful, however, to maintain his humanity as the principal element for their reverence. While they made statues of him these never have a beard, which was the distinct mark of divinity at that time. He is represented as a placid-looking man seated with a scroll on his knees and a look of very sympathetic humanity on his face. For over four millenniums he continued to be held in high honor among the Egyptians, and the hospitals erected in various places were always placed under his protection. When after Alexander's time the Ptolemies, who were originally Greek, came to rule in Egypt, I-em-Hetep came to be identified with Æsculapius, the Greek physician of about 1200 B. C., whose wonderful success in relieving men's ills, bodily and mental, had caused the Greeks after his time, in similar fashion, to make a deity of him.

While I-em-Hetep is the first physician among the Egyptians, he must not be considered an isolated figure in Egyptian history, for every few centuries since we have the story of some distinguished man in medicine whose merits have given him a place in the memory of men ever after. About three centuries after I-em-Hetep came King Athothis, who is said to have written the first text-book of anatomy. A few centuries later came the distinguished surgeon on whose tomb, in the same cemetery of Sakkara or Saqqârah near Memphis, the old capital of Egypt, not far from the present city of Cairo, is to be found the series of pictures of surgical operations which are the earliest extant and which were described in The Journal, Nov. 9, 1907. The Ebers papyrus gives us a still more detailed picture of Egyptian medical life and education, so that it is evident that for about 3,000 years before the writing of this papyrus there was great devotion to medicine and surgery on the part of the men who reached high distinction among their fellows in Egypt. In a word, it is possible, as a consequence of recent discoveries in Egyptian history, to trace the medical profession with its members occupying places of honor and confidence among men for more than 6,000 years.

INDUSTRIAL OVERSTRAIN

While more attention is being continually given to industrial diseases, it is likely to be the feeling of the physician that this is a special field which concerns mostly the practitioner in the industrial centers. Those who have to do with painters or other lead workers are naturally interested in plumbism; other groups will find it to their advantage to study grinder's phthisis, etc. But there is a more general relation of labor that demands the attention of the medical profession and must interest every physician who has patients of the laboring class. While a trade may be free from poisons or other special tendencies to disease, it may contribute to the production of disease by the severe and exhausting character of the labor itself. Josephine Goldmark[1] calls attention to the influence of fatigue and the need of a thorough investigation of its effects in predisposing the system for other diseases, such as the infections. The prevalence of neurasthenia among the working population and the increase of other nervous diseases among tradesmen and laborers are phenomena whose relation to fatigue and long working hours it would be well to investigate. This author calls attention to the lack of study of this subject on the part of American hygienists, although foreign investigators have taken it up and it is receiving emphatic attention from the Permanent International Commission for the Study of Professional Maladies, a French organization on which American medicine has no representative. Attention is called to the fact that the 1910 meeting of the International Congress of Hygiene and Demography, to be held in the United States for the first time, will give an opportunity for the presentation of the results of studies of the effects of fatigue and long hours under American industrial conditions. Such a study would be exceedingly beneficial as a basis for framing suitable laws to regulate such conditions and would also give the medical profession a new insight into the pathogenesis of many common ailments.

---

[3] Rideal: Jour. Roy. San. Inst., 1909, xxx, 32.

Medical News

ILLINOIS

Chicago

Infantile Mortality.—The total deaths of infants under 1 year of age during the past week jumped from 142 to 194, an increase of 52 over the preceding week, and an excess of 13 over the corresponding week of last year. Gastrointestinal disorders are accountable for 185 deaths, or more than 31 per cent. of the total for the week from all causes; 167 of these 185 deaths were among children under 2 years of age. This record exceeds the preceding week by 39, and is 23 higher than the corresponding week of last year. Notwithstanding these increases, the general death rate was more than 4 per cent. lower than the August average and 6.5 per cent. below the rate of the corresponding week of 1908.

MARYLAND

Baltimore

Smallpox on Steamship.—The North German Lloyd steamship *Main* was delayed at quarantine August 10 by the discovery of a case of smallpox among its steerage passengers. After a thorough fumigation, she was allowed to go to her pier. There were 450 passengers aboard the vessel.

Typhoid Decreasing.—The health report for week ending August 14, shows a large falling off in typhoid fever cases. There were 86 cases for the same period in 1908 and 46 in 1909. This result is attributed by the health commissioner to the unusually dry season and the care taken of the city's milk supply.

NEW YORK

Home for Destitute and Sick Children.—The Holiday Farm, organized to maintain a home for the reception and temporary treatment of indigent or destitute sick and convalescent children, was incorporated August 5, with its principal office at Rhinecliff.

No Insurance Company Hospital.—The application of a life insurance company for permission to acquire real estate for the purpose of erecting thereon a tuberculosis hospital has been denied by Superintendent Hotchkiss. The denial rests on the insurance law which does not permit insurance companies to acquire real estate excepting such as is required in the transaction of their ordinary business, i. e., making and selling insurance.

National Tuberculosis Hospital.—It is reported that 27,000 persons in 28 states will contribute a little over 9 cents a month each to build and maintain a tuberculosis sanitarium at Liberty, which is to be established by the Workmen's Circle, a fraternal insurance organization. Immediate steps will be taken toward the erection of the hospital as soon as the application is granted by Health Commissioner Porter. The institution will accommodate 40 patients.

New York City

Gone Abroad.—Dr. and Mrs. W. P. Cunningham, Dr. and Mrs. Samuel G. Gant, Dr. and Mrs. Henry D. Chapin, Dr. and Mrs. Henry B. Delatour, Drs. William E. West and Michele Accetta and Dr. and Mrs. William V. Hayes have sailed for Europe.

Milk Famine Threatens.—The persistent drought throughout New York and the eastern states is responsible for a milk famine, which has already raised the price of milk. Dealers are curtailing their output in every possible way, and a meeting has been called to consider the problem in New York.

Gas Checks for Charity.—From the gas rebate fund, which amounts to about $11,000,000, the committee on the prevention of tuberculosis of the Charity Organization Society has received as a voluntary contribution $14,244. This money will be used by the committee in its crusade against tuberculosis, and will enable the committee to pay for an exhibit to be made in all the schools, preparations for which are now under way.

Work of the Junior Sea Breeze Hospital.—The report of Junior Sea Breeze, a hospital maintained by John D. Rockefeller through the Association for Improving the Condition of the Poor, shows that there have been about twice as many dispensary cases as during the same time last year, while, although the hospital is filled to the extent of its capacity, the total number of admissions has been only about one-half what it was during the same time last summer. While it is admitted that the cool summer may have something to do with the falling off, the real explanation is attributed to the work of the visiting nurses who send the babies to the dispensary before they become dangerously ill. The number of deaths at the hospital has been very small.

Hospital Notes.—Plans have been filed for remodeling the bacteriologic laboratory, improving the lighting and adding accommodations on the first floor of St. Luke's Hospital for animals to be used in experiments. The improvements will cost $25,000.——Plans have been filed for remodeling the upper floor of the City Hospital, Blackwell's Island, and erecting an operating theater. There will be a surgeon's room, a workroom for nurses and an *x*-ray room, together with several recovery rooms. These and several minor improvements will cost $30,000.——Elaborate plans have been approved and a liberal appropriation has been made for the establishment of rest stations, comfort stations and medical stations in all parts of the city during the Hudson-Fulton celebration. One-third of the churches have planned to keep their doors open and to provide nurses from 9 a. m. to 9 p. m. Tents will be put up as emergency hospitals, each containing twelve cots, and nurses, orderlies and physicians will be on duty at all hours. Ambulance launches will be in service during the water celebration.

Buffalo

Personal.—Drs. John Hudson Grant, George A. Himmelsbach and James W. Putnam have gone abroad.

Isolation Hospital Condemned.—Dr. Walter Goodale, superintendent of the temporary Municipal Isolation Hospital, condemns the building, which, originally a public school building, was condemned and abandoned. A site should be provided by the city for a modern hospital for communicable diseases.

Esculapian Club Election.—The Esculapian Club has elected the following officers: President, Dr. Cornelius J. Carr; vice-president, Dr. Irving W. Potter; secretary, Dr. Julius Ullman; treasurer, Dr. Albert J. Colton; and advisory council, the president, and Drs. Francis M. O'Gorman and Frderick S. Hoffman.

Hospital Notes.—Plans have been drawn for an addition to the German Deaconess' Hospital, to cost about $80,000. The addition will be four stories in height, fireproof and will provide 75 new rooms and a well-equipped and complete operating room.——Riverside Hospital, Lafayette avenue, has been enlarged, taking in the Riverside Accident Hospital and the Marine Hospital. The institution is under the charge of Dr. Lillian Craig Randall.

---

[1] The Survey, July 10, 1909.

Academy Elects Officers.—The following officers have been elected for the Buffalo Academy of Medicine: President, Dr. Earl P. Lothrop; secretary, Dr. Harry R. Trick; treasurer, Dr. Lawrence Hendee; trustee, Dr. Grover W. Wende; chairman section on medicine, Dr. Thomas J. Walsh, and secretary, Dr. Henry P. Frost; chairman section on surgery, Dr. Thew Wright, and secretary, Dr. James A. McLeod; chairman section on obstetrics and gynecology, Dr. Burt C. Johnson, and secretary, Dr. James F. Whitwell; chairman section on pathology, Dr. Frederick J. Parmenter, and secretary, Dr. Norman K. McLeod.

NORTH CAROLINA

Personal.—Dr. J. Edward Smoot, Concord, who was operated on for appendicitis at the Salisbury Sanitarium recently, is improving.——Dr. William J. McAnnally, High Point, is seriously ill with septicemia, due to the bite of a spider.——Dr. William Allen, Charlotte, has been elected secretary-treasurer of the Associated Charities of the City of Charlotte.

Impure Mineral Waters.—Under a recently enacted law authorizing the State Board of Health to make examinations from time to time, as it may see fit, of the various mineral waters offered for sale throughout the state, examination of a number of specimens of bottled waters has been made, showing the presence of colon bacilli in a lithia water bottled in Virginia and sold widely throughout the United States.

State Health Officer Commended.—The Medical Society of the State of North Carolina, on the retirement of Dr. Richard H. Lewis as secretary of the Board of Health, adopted resolutions expressing the regret with which they accept his resignation, and its conviction that he has done more, both in his official and individual capacity, than would have been possible for any other one to have done, and commending his work in saving them from impending adverse legislation, and having secured such salutary measures as are responsible for their present advanced position in sanitary work.

State Hospital for Tuberculosis.—The State Hospital for Tuberculosis in Moore county has been visited by the assistant secretary of the State Board of Health, and has been closed pending needed sanitary improvements. The institution is expected to be opened next month with accommodation for 50 patients, and after January 1 next accommodation for 50 additional patients will be provided. A strong sentiment exists among leading phthisiologists of the state that the present site for the institution should be abandoned, and a new location secured in the mountain section of the state.

NORTH DAKOTA

New Hospital Opens.—Dedicatory exercises of the Bismarck Hospital and Deaconess Home were held July 4. The hospital is a three-story structure, 40 x 120, and is well built and thoroughly equipped.

Physician Wins Suit.—In the suit against Dr. Edward J. Hagen, Williston, in which damages were claimed on account of alleged malpractice, the jury, after five hours' deliberation, brought in a verdict in favor of the defendant.

Sanitarium News.—Bottineau, Dunseith, Cando and Walhalla are working to secure the State Sanitarium for Tuberculosis, recently authorized by the legislature.——Bids were opened and the contract let on July 24 for the new $10,000 addition to the Fargo Sanitarium.

OHIO

Personal.—Dr. Paul W. Tappan, Dayton, has been elected first lieutenant O. N. G.——Drs. W. Watson Conger, Toledo, William P. Love, Youngstown, and Adolph J. Girardot, Toledo, have been taking the course of instruction at the Government School, Sparta, Wis.——Dr. R. H. Bishop, Jr., has succeeded Dr. Frank Vincent as a member of the staff of the Tuberculosis Dispensary, connected with the Western Reserve University Medical School, Cleveland.——Dr. William J. Means, Columbus, was seriously injured in an automobile accident, July 16.——Dr. and Mrs. George F. Brubaker, Springfield, have sailed for Europe.——Dr. Louis M. Early, physician of the State School for the Blind, Columbus, has retired and has been succeeded by Dr. Isaac B. Harris.

Cincinnati

Roentgenologists Meet.—Medical men, interested in *x*-ray work, met August 7, at the office of Dr. Henry Kennon Dunham and organized the Cincinnati Roentgen Ray Society, with seven charter members. Dr. Dudley Webb was elected secretary.

PENNSYLVANIA

State Medical Society Meeting.—The annual meeting of the Medical Society of the State of Pennsylvania will be held in Philadelphia, September 27 to October 1.

Tablet Presented to Hospital.—A bronze tablet of the late Dr. John Fay is to be presented to the Altoona Hospital to be placed in the reception room early next week. Addresses will be made on behalf of the staff by Drs. William S. Ross and Frederick H. Bloomhardt, Altoona, Dr. Henry H. Brotherlin, Hollidaysburg,and others.

Hospital Notes.—St. Margaret's Memorial Hospital, which was equipped for service ten years ago, but has been unused since that time because of the lack of a maintenance fund, is soon to be opened. The hospital has a capacity of 100 patients.——The president of the Bethlehem Steel Works has ordered the closing of the Bethlehem Steel Works Hospital.

State Board of Examiners for Nurses.—The examining board for nurses, appointed under the act passed in the last legislature, consists of Miss Ida F. Giles, Pittsburg, Miss Roberta M. West, Erie, and Drs. Alice M. Seabrook, William S. Higbee and Albert E. Blackburn, all of Philadelphia. The board met for organization at Harrisburg, July 27, and elected Dr. Higbee, president; Miss West, vice-president, and Dr. Blackburn, secretary-treasurer. The board is now ready to receive applications for registration in compliance with the act, through its secretary.

Personal.—Dr. Samuel H. Gilliland, Marietta, has sailed for Europe.——Dr. Percival A. Herman, Middleburg, has been appointed a medical inspector in the department of tuberculosis of the State Health Bureau.——Dr. Hamilton K. Beatty, Pittsburg, superintendent of the sanitation bureau of the City Health Department, was presented, July 7, by the chief inspectors of the stations over which he presided, with a gold shield.——Dr. J. William Schultz, Tremont, has been elected president and Dr. Theo. C. Fegley, Tremont, secretary of an organization composed of the physicians in the territory extending from Pine Grove to Hegins.——Dr. Mary M. Wolfe, resident physician to the State Hospital for the Insane, Norristown, has resigned, to take effect October 1.——Dr. Wilmer R. Batt, Harrisburg, one of the three representatives of the United States at the meeting of the International Commiission for the Revision of the Classification of Causes of Death and Illness, has sailed for Europe.

Philadelphia

Clinic Opens in New Location.—The Philadelphia Clinic for the Free Treatment of Throat and Chest Diseases has removed to its new quarters at 2114 Lombard street. Free clinics are held at the institution on Mondays, Wednesdays and Fridays at 3 p. m.

Personal.—Drs. Henry R. M. Landis, Charles K. Mills, Eugene L. Van Sant and John McLernon have sailed for Europe.——Dr. Sheridan P. Manship has been appointed a police surgeon.——Dr. Walter W. Roach has succeeded Dr. William Graton, resigned, as medical inspector.

Bequests to Tuberculosis Sanitaria.—Payment of the $5,000 bequest of John G. Brill to the Free Hospital for Poor Consumptives, White Haven, have been made by representatives of the estate.——Dr. Lawrence F. Flick, director of the Phipps Institute, has received an offer from one of the Philadelphia hospitals of six beds, the expense of which will be paid by Henry Phipps.

Christmas Stamp Money Apportioned.—The funds received from the sale of Christmas stamps for the tuberculosis cause have at last been apportioned as follows: Free Hospital for Poor Consumptives, White Haven, $2,500; Pennsylvania Society for the Prevention of Tuberculosis, $1,000; Germantown Hospital, $1,500; Grandview Institution for the Cure and Treatment of Tuberculosis, $1,000, and Philadelphia Protestant Episcopalian City Mission Home for Consumptives, Chestnut Hill, $2,000. The committee recommended that the balance of more than $3,000 be retained for distribution to tuberculosis institutes which have not yet applied for relief.

TEXAS

New Sanitarium.—Dr. Andrew J. Bell and associates are to erect a twenty-room sanitarium at Quanah, to cost $10,000.

Building for Doctors.—The Dallas Medical and Surgical Building Association has been organized to erect an office building to be devoted to professional men entirely and to cost $500,000.

Acquitted.—In the district court at Rusk, July 3, a jury returned a verdict of not guilty in the case of the State vs. Dr. J. J. Lockhart Forest, charged with the murder of Ollie Branch, about two years ago.

Personal.—Dr. William M. Brumby, Austin, president of the State Board of Health, has returned from a trip of inspection to Cuban, Central American and Mexican ports, and reports great progress in sanitation.——Dr. John W. Tottenham has been appointed health officer of Brownwood.——Dr. John H. Florence, Galveston, has been acting as state health officer during the absence of Dr. Brumby.——Dr. G. W. Basket, Van Alstyne, has been elected medical director of the Texas Homeo. Sanitarium, Llano.

UTAH

Faculty Changes.—Leon W. Hartman, associate professor of physics, and William Blum, assistant professor of chemistry, have severed their connection with the University of Utah.

Sanitary Bulletin.—Dr. Theodore B. Beatty, Salt Lake, secretary of the State Board of Health, has issued an imperative bulletin to all health officers of the state, in which he urges them to use the utmost vigilance in the enforcement of the law requiring the disinfection of all discharges from typhoid fever patients.

New Hospital.—The contract for the construction of the Dee Memorial Hospital, Ogden, has been awarded for $75,000. The building, when completed and equipped, will have cost more than $100,000. It will be five stories in height, 149x60 feet, will contain accommodation for eighty patients, and is to be completed by February 1, 1910.

Care for Veterans.—Dr. William F. Beer, in charge of the forty-third annual encampment, G. A. R., Salt Lake City, has arranged for a thoroughly-organized medical and nursing corps to furnish first aid and provide medical attention for all cases of illness and accidents during the encampment. An emergency hospital has been secured in the Boston Building and a special retention hospital has been arranged on the grounds of the Latter Day Saints Hospital. Automobile ambulances are to be placed at various stations along the line of march.

VERMONT

Alumni Election.—The annual meeting of the Alumni Association of the medical department of the University of Vermont, Burlington, was held June 29, and the following officers were elected: President, Dr. U. A. Woodbury, Burlington; vice-presidents, Drs. William N. Bryant, Ludlow; Patrick E. McSweeney, Burlington; Michael F. McGuire, Montpelier; Charles L. Fletcher, Dover, N. Y.; and Don D. Grout, Waterbury; and, secretary-treasurer, Dr. Lyman Allen, Burlington.

Society Meetings.—At the annual meeting of the Lamoille County Medical Association, held in Burlington, July 28, the following officers were elected: President, Dr. George L. Bates, Morrisville; vice-president, Dr. Harry W. Barrows, Stowe; secretary-treasurer, Dr. William M. Johnstone, Morrisville; censors, Dr. W. M. Johnstone, Morrisville, John C. Morgan, Stowe, George H. N[illegible] uditor, Dr. George L. Bates, Morrisville; [illegible] state society, Dr. Archibald J. Valleau, [illegible] annual meeting of the Addison County Association, held in Middlebury, July 22, the following officers were elected: President, George F. B. Willard, Vergennes; vice-president, Dr. Robert W. Prentiss, East Middlebury; secretary, Dr. Frank C. Phelps, Vergennes; treasurer, Dr. Frank T. Briggs, Bristol; and librarian, Dr. Merritt H. Eddy, Middlebury.

VIRGINIA

Sanatorium Opens.—The new State Sanatorium for Tuberculosis at Roanoke Red Sulphur Springs, was opened to receive patients July 16.

Medical Society Organized.—Ocean View Medical Society has been organized at Norfolk, with the following officers: Dr. Southgate Leigh, Norfolk, president, and Dr. Wiilliam D. Turner, Shoal Bay, secretary.

Medical Society Meets.—The Fairfax Medical Society held its annual meeting in Alexandria August 5, and elected the following officers: President, Dr. Frederick M. Brooks, Swetnam; vice-presidents, Drs. C. R. DuFour and Carlton L. Starkweather, Occoquan; secretary, Dr. Llewellyn Powell, Alexandria; corresponding secretary, Dr. Arthur G. Coumbe, Vienna, and treasurer, Dr. Edwin L. Detwiler, Herndon.

Personal.—Dr. Kenneth Bradford has been elected health officer of Staunton.——Dr. Truman A. Parker, Richmond, has been placed in charge of the new Catawba Sanatorium for Tuberculosis, in Roanoke County.——Drs. George J. Williams, Newport, Will R. Williams, Richlands, Lomax Gwathmey and Herbert N. Old, Norfolk, have sailed for Europe.——Dr. Henry Stuart MacLean has been appointed *chief surgeon for the* Virginia Railway and Power Co., and Dr. Francis W. Upshur, assistant, for Richmond and Manchester, and Dr. John G. Rennie has been appointed local surgeon at Petersburg.

WEST VIRGINIA

Antituberculosis Society Organized.—The Antituberculosis League of Parkersburg was organized August 2 with nonprofessional officers, but with Drs. Alfred N. Frame, Walter S. Link and O. Dustin Barker on the board of directors.

Personal.—Dr. W. Dewitt Stewart, city health officer of Moundsville and Dr. Charles W. Hudson, health officer of Parkersburg, have resigned.——The diploma of Dr. James F. York, Huntington, issued by the Eclectic Medical Institute, Cincinnati, June 4, 1895, has been stolen from his office.

Smallpox Prevented.—Dr. J. F. Scott, president of the board of health of Henry, reports a case of smallpox imported by an Italian immigrant, which by reason of prompt diagnosis and quarantine by Dr. R. M. Riley, was followed by no spread of the disease.

WISCONSIN

District Society Meeting.—At the sixth annual meeting of the Second Councilor District Medical Society, held in Kenosha, August 3, the following officers were elected: President, Dr. Samuel C. Bochan, Racine; secretary-treasurer, Dr. George W. Nott, Racine, and vice-presidents, the presidents of the affiliated county societies. The next meeting will be held in Racine.

Faculty Announced.—The Wisconsin College of Physicians and Surgeons, Milwaukee, announces that its first semester will open October 5, and the following faculty list is given: Dr. Wilbur O. Carrier, president; Dr. Thomas C. Phillips, dean; Dr. Solon Marks, emeritus professor of military surgery and of fractures and dislocations; Dr. A. Hamilton Levings, professor of surgery; Dr. Uranus O. B. Wingate, professor of nervous and mental diseases; Dr. William H. Washburn, professor of medicine; Dr. James A. Bach, professor of ophthalmology; Dr. Harry A. Sifton, professor of clinical surgery; Dr. Lorenzo Boorse, *professor of pediatrics*; Dr. Gustav A. Kletesch, professor of gynecology; Dr. Henry Blank, professor of orthopedic surgery; Dr. Thomas C. Phillips, dean of the faculty, professor of ophthalmology and otology; Dr. William Francis Becker, professor of mental and nervous diseases; Dr. Gustav A. Hipke, professor of obstetrics; Dr. Herman Reineking, professor of surgery; Dr. Henry B. Hitz, professor of rhinology and laryngology; Dr. Frank E. Darling, professor of bacteriology; Dr. Louis F. Rauschaupt, professor of chemistry; Dr. James D. Madison, professor of medicine; Dr. Curtis A. Evans, professor of anatomy; Dr. Emerson Armour Fletcher, professor of genitourinary surgery; Dr. George C. Ruhland, professor of pathology; Dr. Milton M. Spitz, professor of therapeutics; Dr. Otto H. Foerster, professor of dermatology; Dr. Wilmot F. Miller, professor of electrotherapeutics and associate in neurology; and Dr. Henry Hasson, professor of clinical microscopy.

GENERAL NEWS AND COMMENT

Railway Installs Paper Cups.—The Baltimore and Ohio Railway has installed one of the new systems of individual drinking cup machines at both Camden and Mt. Royal stations, Baltimore. The cups are made of white paraffin paper, and arranged in slot machines. By dropping a cent in the slot, a paper cup is dropped into the hand and becomes the property of the user.

Branch Federal Laboratory to be Established.—The Public Health and Marine-Hospital Service has taken steps looking to the establishment of a branch of its Federal Laboratory on the Pacific Coast in the zone of squirrel plague infection. This branch laboratory will have for its special purpose the elucidation of the various problems in connection with plague and rodents, work which can not safely be performed in laboratories in the great centers of population.

FOREIGN

Allegory in Sculptured Memorials to Scientists.—Several statues of prominent members of the profession in Europe have been installed recently as memorials at the scene of their labors, but the designs of the sculptors have all been ornately allegorical, and many criticisms have been made that this conflicts with the simplicity and love of absolute truth which distinguished the scientists thus honored. The Brouardel statue at Paris is a bust of the scientist on a tall pedestal with two graceful female figures below, Forensic Medicine and Hygiene, a little smaller in proportion than the bust, lifting high a garland to wreath it at the base of the bust. It stands in the grounds of the medical school. The Mikulicz memorial at the surgical clinic at Breslau represents in bas relief Mikulicz seated in profile, while two standing female figures, Medicine and Science, of a size rather dwarfing the recipient, are placing the wreath of immortality on his brow. One can not help imagining that Mikulicz feels.. [illegible] the situation. The Kussmaul memorial is [illegible] than life-size hewn out of the stone forming the base of the memorial, with a smaller allegorical bas relief below of Medicine relieving a sick youth. The allegorical design has run riot in the Virchow statue, which is to be merely a statue of Hercules overcoming the Nemean lion, representing Virchow's conquest of disease. There is nothing to suggest Virchow personally except a small bas relief bust below. Something like the simple grandeur and life-like presentation of a St. Gauden's statue of Lincoln is what the friends of the scientists long for as a much more appropriate tribute to the memory of men of science, perpetuating their personality, but the sculptors, as a rule, seem determined to insist on decorative allegorical designs.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Aug. 7, 1909.

Premature Burial

As stated in a previous letter the coroner's inquest of Great Britain, like many others of its institutions, is antiquated. A committee of the House of Commons is now considering the subject and the trite but ever-interesting subject of premature burial is one of the topics which came up. Mr. Pepper, of St. Mary's Hospital, the well-known medicolegal expert, gave evidence. He said that under the present condition of death certification there was practically no danger of any one being buried alive. Nearly all the cases of premature burial were myths. He regarded the present scare on the subject as baseless. A muscular movement of a corpse possibly was the basis of some of the reports. But he thought that no person ought to be buried until the corpse had been seen by a physician and no physician ought to give a certificate until he had seen the corpse. According to the present system a medical man may give a death certificate if he has never seen the corpse; all that is necessary is that he should have been in attendance during the last illness and seen the patient within a week of death.

Malaria Without the Anopheles Mosquito?

A despatch received from the governor of the Seychelles Archipelago—which lies about 750 miles northeast of Madagascar—appears to show that an epidemic of malaria is possible without the agency of the anopheles mosquito. In April, 1908, malaria broke out suddenly in Picard Island. The cases were of the benign tertian type mixed with a few isolated quotidian ones and occurred up to the end of August. Almost all the laborers in the settlement were attacked, but none died. The diagnosis was confirmed by microscopic examination of the blood which was performed by Dr. M. S. Power. Under quinin the epidemic soon subsided. It began soon after the arrival of a vessel from Manhigo, a French island off Madagascar, where malaria is prevalent. Some laborers suffering from malaria landed from the vessel and within a month the disease spread to others. Careful search for the anopheles was made but failed to reveal it. At first this was attributed to the season, as mosquitoes are scarce during the southeast monsoon. However, larvæ of the culex and stegomyia were found. Further search for the anopheles during and after the rainy season was made for five months, but it could not be found. The conclusion was drawn that it does not exist in Picard Island. Previous investigators have also recognized the absence of this mosquito from the Seychelles Islands and malaria has been unknown there excepting imported cases, but these were not known previously to have given rise to fresh cases. Two suggestions have been made. Perhaps under certain circumstances malaria may be conveyed by other mosquitoes than the anopheles. Perhaps the vessel in which the malarial laborers arrived may have carried some anopheles which went ashore and bit the inhabitants, but, the local conditions not being favorable to their existence, they disappeared.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Aug. 5, 1909.

Prize of the Academy of Sciences

The Academy of Sciences has just awarded three prizes of $500 (2,500 francs) each, one to Dr. Neumann for his researches on the family of the ixodidæ and on various groups of parasites of the superior vertebrates; one to Dr. Charles Nicolle for his works on infantile kala-azar; and one to Prof. J. Bergonié and Dr. L. Tribondeau of Bordeaux for their work on Roentgen rays and fulguration. In the same competition three second prizes of $300 (1,500 francs) each were awarded, one to Prof. H. True and Dr. P. Chavernac of Montpellier for their work on ocular hygiene and ophthalmologic inspection of schools; one to MM. C. Porcher and C. Hervieux for their "Investigations on Indol and Some of Its Derivatives;" and one to M. Moussu, professor at the National Veterinary School of Alfort, for his "Investigations on the Tuberculosis of Cattle." The Godard prize ($200) was awarded to Dr. Pousson, professor at the College of Medicine of Bordeaux, for his "Surgery of Nephritis." The Bellion prize ($280) was awarded to Dr. C. Nicolas, resident physician of Lifu, New Caledonia, for his work, "Public and Private Hygiene of the Kanakas of the Loyalty Islands." The Bréant prize ($20,000), offered for a cure for Asiatic cholera, was not awarded; but out of the accumulated interest of this fund the academy awarded a prize of $800 to W. M. Haffkine for his works on vaccination and bubonic plague, and a second prize of $200 to Dr. Louis Rénon, physician of the hospital of Paris, for his work entitled "Practical Treatment of Pulmonary Tuberculosis."

Personal

The chair of therapeutics of Bordeaux has just been replaced by a clinical department of cutaneous and syphilitic diseases, of which Dr. Dubreuilh, adjunct professor, has been appointed head. At the same college the chair of operative medicine has been replaced by a clinical department of diseases of the urinary passages, and Dr. Pousson, an adjunct professor, has been appointed as its head.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, July 29, 1909.

The First Provincial Institution for Tuberculosis

The first provincial institution for the treatment and prophylaxis of tuberculosis has just been founded in Göttingen, and has already proved to be a necessity, for in several places in the district tuberculosis is very prevalent. The clergy of the district have undertaken the local direction of the institution. Its objects are twofold: first, to eradicate the various foci of tuberculosis; and, second, to discover incipient cases of tuberculosis and to furnish institutional treatment to the patients. Sputum cups may be obtained for distribution. The washing of the patients is to have special treatment in laundry bags, the property of the institution. Strengthening foods (milk and eggs) are to be furnished in special cases. The effort will be made to see that tuberculous patients with sputum capable of conveying infection shall have separate sleeping-rooms or at least separate beds in their homes. The disinfection of the dwelling will also be done by the institution. The funds for the new institution have been raised and placed at the disposal of the local commission by the life insurance organization.

Investigation of the Influence of Roentgen Rays on Physical Growth

It has been established through animal experimentation that exposure to Roentgen rays impairs physical growth. To investigate the question how far these findings apply to human beings, this year's congress of the German Roentgen Society has decided on a collective inquiry. Children who have been treated with Roentgen rays during their first year, especiallly those whose treatment took place some time ago, are to be investigated, for it has been shown by animal experimentation that the disturbance in growth is greater the younger the animal, and also that a slighter degree of disturbance of growth may not manifest itself until after several years.

VIENNA LETTER

(From Our Regular Correspondent)

VIENNA, July 30, 1909.

Death of Hofrath von Vogl

A few days ago August von Vogl, emeritus professor of pharmacology in Vienna, died at Bozen in his seventy-sixth year. The remarkable personality of this scientist is well known, as he was the originator and founder of the modern pharmacognosy; he was the first man to apply the researches of histology and the use of the microscope to this branch of medicine; and his pupils are scattered all over the world. Von Vogl obtained the degree of M.D. in 1860, being the first man in Austria to obtain it. (Formerly only surgeons or physicians or "accoucheurs" (masters of obstetrics) were entitled to practice, each one his own specialty.) Von Vogl soon took up the study of pharmacology and materia medica, became privat docent and a short time afterward professor of this branch, and in 1879 he was appointed ordinary professor of materia medica in Vienna. In 1897 he became president of the *Oberste Sanitätsrat* (chief board of health in this country). He was elected twice as "rector magnificus" of the Vienna University, and was appointed by the emperor as Hofrath (privy councilor), and finally ennobled. When he retired from university life at 70, his duties were divided among his pupil and successor, Prof. Hans Horst-Meyer, and Professors Schattenfroh and Mitlacher; such was the enormous amount of work accomplished by this one man. The chief books of the deceased are a text-book on materia medica (translated into seven languages), an anatomic atlas of pharmacognosy (a commentary on the pharmacopeia of different countries), and a work on the adulteration of food, especially of flour, condiments and fruits. Among other distinctions he possessed the English Hanbury medal. von Vogl sometimes used to say he had examined more than 50,000 specimens under the microscope. He was a severe but kind examiner of the students, and none bore him a grudge.

Correspondence

Dr. Harvey Cushing's Oration on the Hypophysis Cerebri

To the Editor:—Those who expressed surprise when, over six years ago ("Internal Secretions," 1st Ed., 1903), I asserted that the anterior lobe of the pituitary played a leading rôle in the vital process *per se*, must now acknowledge the far-reaching meaning of Dr. Cushing's statement, in the Oration on Surgery, published in The Journal, July 24, that "more than one hundred total or partial hypophysectomies" had shown that "the anterior lobe of the hypophysis is a structure of such importance that a condition of apituitarism is incompatible with the long maintenance of life." While fully acknowledging the great value of Dr. Cushing's experiments, however, I must take exception to his conclusion that they sustain the theory that it is by means of a secretion capable of influencing the organism at large that the anterior pituitary carries on these all-important functions.

That extracts of the posterior lobe raise the blood pressure, slow the heart and promote diuresis, is certain, but I maintain that these effects are not produced by a true secretion, but by a mere component of the organ similar to that which, in extracts of the kidney, testis, ovary, etc., produces identical effects. As I have shown recently (*Monthly Cyclopedia*, June and July, 1909), these effects are those of adrenal extracts, and have long misled observers into believing that these various organs produced internal secretions (See "True *versus* Pseudotherapy," in a forthcoming number of the *New York Medical Journal*). Additional, but as yet unpublished, researches have suggested, moreover, that this was due to the presence in the pituitary, as well as in all the above-mentioned organs, of cellular elements, the so-called "adrenal rests" (not aberrant cells from my viewpoint, but activators of local metabolism), which are well known to give rise, especially in the kidney, to hypernephroma. Dr. Cushing, in fact, compares the action of the so-called pituitary secretion to that of adrenalin.

Again, although Herring's view that the colloid fluid (laden with broken-down cells, let me add) passes upward is quite warranted, this does not prove in the least that it is a true secretion. Indeed, Dr. Cushing's own text suggests the contrary. Since the blood pressure raising substance is "confined, as Howell has proved, to the posterior lobe," why is it that, as Dr. Cushing says, "after this portion of the gland has been removed, there is no apparent disturbance with the physiologic balance of the body?" Everyone knows that removal of the adrenals or of the thyroid, which produce true secretions, causes marked and even fatal disturbances. Again, the anterior pituitary is regarded by Dr. Cushing as the original source of this secretion; why is it that its extracts are inert? Can we consistently, with him, ascribe acromegaly, overgrowth, etc., to "hypersecretion," and dystrophia adiposogenitalis, Dercum's adiposis dolorosa, etc., to "hyposecretion" of this inert substance? These are but few of the many directions in which the secretion theory blocks all progress.

Permit me to state that such is not the case when the functions I have ascribed to the pituitary, after a far more searching study than has ever been given it by physiologists, are taken into account. The anterior lobe (including its nerve cells) from this viewpoint is connected with the floor of the third ventricle (Ramon y Cajal, Genti's) and the pons (Andriezen) by nerves which can be traced, both physiologically and clinically, to the adrenals and thyroid, while the secretions of these organs, as I have shown by many incontrovertible facts, are active factors in oxidation, metabolism and nutrition. Under these conditions it is plain that any morbid activity of the anterior pituitary, whether caused by hyperemia, hypertrophy, tumor, etc., must, by exciting unduly the adrenals and thyroid, cause excessive nutrition, overgrowth, and even giantism. Have we not the giantism of childhood in adrenal hypernephroma and rapid growth in the cretin under thyroid extract? Conversely, destructive or debilitating disorders of the anterior pituitary, by lowering the activity of the adrenals and thyroid, must necessarily entail small stature with deposition of fat and adiposis dolorosa. Do we not use thyroid extract in obesity? Do we not witness also, as symptoms of degeneration of the pituitary, myxedema, lowered oxidation, hypothermia and bronzing? Page after page of perplexing queries could be submitted attesting pointedly to the fact an imported doctrine is not always invulnerable.

All this does not militate in the least against Dr. Cushing's researches or the correctness of his surgical conclusions. His experimental and surgical work is entitled to the greatest appreciation; but it is precisely because I value his work so highly that I would like to see it devoted to the development of something besides mere assumptions.

C. E. de M. Sajous, Philadelphia.

High Enemas—Can a Tube Be Passed Into the Colon?

To the Editor:—In connection with Dr. Horace W. Soper's paper on page 426, and your editorial on page 464 of The Journal, August 7, I wish to express my appreciation of Dr. Soper's ingenuity and industry, displayed in the scanning of foreign literature. From page 48 of the third edition of Jacobi's "Therapeutics of Infancy and Childhood," I beg to quote as follows: "The great normal length of the sigmoid flexure in the infant and child, which results in its being bent on itself, prevents the introduction of an instrument to a considerable height. It will bend on itself." On page 343 one may read: "The condition of the sigmoid flexure renders the introduction of the instrument beyond the very beginning of the sigmoid flexure, a perfect illusion in many cases. It often happens that an elastic or flexible tube, when introduced to or beyond the third sphincter, bends on itself and reappears at the anus. To facilitate the entrance of the liquid into and beyond the sigmoid flexure, the irrigation should be made slowly and gently, while the pelvis of the infant is raised. The nozzle must be smooth and not thin." Similar statements are found in Jacobi's "Intestinal Diseases of Infancy and Childhood," 1887. The abnormal length and flexures of the sigmoid colon which lend to what Jacobi has called "Congenital Constipation," were first described by him in 1869.

In an article on "Congenital Constipation," which appeared in the Transactions of the American Pediatric Society, vol. vi, page 41 (1894) I wrote as follows: "The article by Jacobi, 'Some Important Causes of Constipation in Infants' is classical, and though it appeared in 1869 (*Am. Jour. Obstet.*, vol. ii), it will repay careful reading and study at the present time." During the twenty-five years of my college assistantship, Dr. Jacobi has annually referred to the difficulty or impossibility of passing elastic or solid tubes through the sigmoid flexure. When felt below the liver, the instrument is not in the transverse colon, but in the sigmoid, which has simply been raised to an abnormal position.

Francis Huber, M.D., New York City.

To the Editor:—Having observed in The Journal of Aug. 7, 1909, the article by Horace W. Soper, M.D., of St. Louis, I wish to call attention to the enclosed extracts from a paper read by me before the American Proctologic Society in June, 1904, entitled, "The Present Status of the Flexible Rectal Tube, Which Should be Paraphrased Non-utility and Impracticability." I make this request in order that the society may be placed in a proper light before the profession, as having taken the initiative in this matter.

> "The members of our society generally have definitely accepted the existence and functions of Houston's rectal valves, we have dilated on their pathologic conditions, but have not reflected what effect they must have on the use of the flexible rectal tube. . . . I venture to assert, that notwithstanding all of our boasted knowledge with regard to these valves, that it is the universal practice with rectal specialists, when ordering or giving a high enema, to use the long rectal flexible tube.
>
> "It occurred to me that if the pathologic function of these valves is to shelve and ease down the fecal matter, and if in a pathologic condition they could become so thickened as to form an obstruction to the passage of the fecal matter, that they must interfere materially with the passage of the rectal tube beyond them. I therefore instituted a series of experiments with the soft rubber tubes, to ascertain the true state of affairs. In a number of instances I introduced the rectal tube, then passed in Tuttle's proctoscope over it, and on turning on the electric light, I found, as I had expected, *the rectal tube coiled on itself in the lower portion* of the rectum, between the first valve and the anal margin. I have not yet found a single exception to this condition, although, I am willing to admit that occasionally it may pass them. This I should regard more as an accident, than an intended result. . . .
>
> "*But why should we depend on such uncertain means, and one* attended with so much difficulty in its use, when we always have one, that is so much easier and certain to accomplish the purpose. I refer to the application of the physical law of gravity. A patient should be placed in the knee-chest position, or if too weak, in Sims' position, with the head and shoulders lowered, and the hips elevated with a pillow. The high enema can be given in this position with the most satisfactory results, using a short rectal nozzle. Even in cases of impaction, the water so introduced can be made to distend the bowel, and get beyond the point of obstruction, by sufficiently elevating the bag. By using a large quantity of water, it can be made to run around as far as the ascending colon."

Samuel T. Earle, M.D., Baltimore.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

HISTORY OF THE LEUCOCYTE MIGRATION

To the Editor:—Who first saw the emigration of leucocytes through the capillaries, or stated that the polymorphonuclear cells of inflammatory exudates were emigrated from the blood-vessels? *Ludwig F. Guldner*, Davenport, Iowa.

Answer.—Adami, in his monograph on "Inflammation" (Macmillan and Co., 1907) gives the history of this discovery as follows: "By his researches, Cohnheim (1867) forcibly attracted the attention of pathologists to the diapedesis of leucocytes in inflammation —a process which had already been very clearly described years before by W. Addison (1843) and Waller (1846) in England, and yet earlier (though without grasp of the connection between the diapedesis and inflammation) by Dutrochet (1828) in France."

FLECHSIG TREATMENT OF EPILEPSY

To the Editor:—In The Journal, August 7, page 494, is a paragraph in which is mentioned the Flechsig opium-bromid and baths method of treatment. Please give the details.

J. H. Reed, M.D., Sharon, Pa.

Answer.—We have received several similar letters asking for details of this method of treatment, concerning the merits of which the various authorities on nervous and mental diseases disagree. The treatment is practically abandoned now, on account of the little benefit obtained in comparison with the dangers run. The Flechsig method is to administer opium for a short time in enormous doses, then to stop it abruptly and follow with large doses of bromids. Ordinary pulveris opii is administered in ascending doses up to 0.3 gm. (5 gr.) three times a day, the maximum quantity being reached as soon after the beginning of the administration as possible. The patient is kept on this maximum dose for six weeks; at the end of that time the opium is stopped abruptly and bromid of potassium or sodium to the quantity of 2 drams daily is given. After a few weeks, varying according to the evidences of bromism produced, the quantity is reduced one-half, and later may be diminished to 30 or 40 grains, and in some cases even less than this in the twenty-four hours. The opium is regarded as a preparation for the bromid treatment. Flechsig warns that the patient should be watched throughout the course of opium administration as one suffering from an acute disease.

H. A. Hare in the 1907 edition of his "Practical Therapeutics" states that the frequency and severity of the fits are materially reduced in this way for several months in some cases but that it does not cause a cure. It succeeds best in old cases and is not useful in recent ones. In the 1901 edition of his "System of Practical Therapeutics" he says: "After a year or two, if the attacks are not kept in abeyance, the opium may be repeated. I have yet to see any detrimental results or sequences of employing this method."

Gowers in his work, "Epilepsy," 1901, asserts that he regards it as doubtful whether the subsequent administration of bromid in such large doses has more influence than it would have without the preceding course of opium. The benefit sometimes seen in old obstinate cases of epilepsy, he says, may be explained by the large doses of bromid administered after a period of freedom from its influence.

Oppenheim, in "Diseases of the Nervous System," 1900, p. 783, says: "On the whole, the results of this treatment are very doubtful, and, in addition, it is not harmless, does not suit those of weakened constitutions, and demands careful watching, and is therefore probably only practicable in a hospital."

Starr, in "Nervous Diseases, Organic and Functional," 1907, p. 755, says: "I have not had good results from this course of treatment. I have known the opium habit to be induced. It is a method which is falling into disrepute. Opium and morphin should be avoided in epileptics."

Mettler, in "Diseases of the Nervous System," 1905, p. 220, says: "The plan is of doubtful efficacy and its dangers are not insignificant. In my own experience, though limited, it was not superior to the use of the bromids alone."

Spratling, in "Epilepsy," 1904, p. 374, states: "Flechsig recommended this treatment only in chronic cases in which the bromids alone had failed and cautions that the patient be carefully watched during the whole course of treatment. In my experience the plan was of little use. . . . The verdict of those who have tried the method is almost uniformly unfavorable, including Donath, Bohme, Landois, Luske, Rathe, Homen, Lichen, Warda, and Bratz."

The Public Service

Medical Department of the Army

Memorandum of changes for week ended August 14, 1909:

Skinner, G. A., major, ordered to Ft. Lawton, Wash., for duty on arrival from San Francisco.

Reynolds, C. R., major, relieved from duty at the Walter Reed General Hospital, Washington, D. C., and ordered to Washington, D. C. for duty.

Shepard, J. L., capt., ordered to duty with militia field exercises, Massachusetts coast, August 14 to 21.

Hartnett, E. H., major, granted leave of absence for 10 days.

Glennan, J. D., major, O'Connor, R. P., capt., Brechemin, Louis, Jr., capt., and Smith, H. M., capt., relieved from duty in the Philippines Division in time to sail Nov. 15, 1909, from Manila, P. I., for San Francisco, Cal.

Baker, F. C., major, ordered to Governor's Island, N. Y., for duty during the maneuvers in Massachusetts, August 14 to 21.

Juenemann, G. F., capt., relieved from duty at Fort McDowell, Cal., and ordered to Fort Logan, Colo., for duty.

Wickline, W. A., capt., ordered to accompany troops from San Francisco, Cal., to Washington Barracks, D. C.

Suggs, Frank, M. R. C., ordered from Fort Niagara, N. Y., to Fort Porter, N. Y., for temporary duty.

Brown, W. E., M. R. C., granted sick leave of absence for six months.

Jackson, T. W., M. R. C., when relieved at Washington Barracks, D. C., ordered to Fort Hunt, Va., for duty.

Hart, J. W., M. R. C., when relieved at Fort Hunt, Va., ordered to Henry Barracks, Cayey, P. R., for duty.

Wallace, G. I., M. R. C., when relieved at Henry Barracks, Cayey, P. R., ordered to Fort Sam Houston, Texas, for duty.

Coffin, H. L., M. R. C., relieved from duty on the transport *Burnside*, and ordered to Vancouver Barracks, Wash., for duty.

Eber, A. H., M. R. C., granted sick leave of absence for 2 weeks.

Usher, F. M. C., major, granted leave of absence to and including Sept. 1, 1909.

Wertenbaker, C. I., M. R. C., relieved from duty at Fort Wadsworth, N. Y., and from temporary duty at Fort Terry, N. Y., to take effect on the arrival at the latter post of Major Chandler P. Robbins, M. C., and will then proceed to Fort Jay, N. Y., for duty, relieving Capt. S. J. Morris, M.C., who on being relieved will return to his proper station, Fort Washington, Md.

Clarke, J. T., and Bratton, T. S., majors, relieved from duty as members of the board of medical officers, appointed to meet at Fort Crook, Neb., and Fort Des Moines, Iowa, respectively, for the purpose of conducting examinations of applicants for appointment to the Medical Reserve Corps.

Wells, F. M., M. R. C., ordered to Fort Leavenworth, Kan., for duty with troops to be ordered to Des Moines, Iowa.

Church, J. R., major, left Fort Robinson, Neb., with troops on practice march.

Smith, A. M., major, ordered to Presidio of Monterey, Cal., for duty.

Gunckel, G. I., dental surgeon, ordered to Fort Oglethorpe, Ga., for one month.

Medical Corps of the Navy

Changes for the week ended August 14, 1909:

Rodman, S. S., commissioned surgeon, with rank of lieut. commander, from Dec. 11, 1908.

Peck, A. E., commissioned surgeon, with rank of lieut. com-
mander, from June 12, 1909.

Smith, C. G., commissioned surgeon, with rank of lieut. commander, from July 1, 1909.

Brooks, F. H., commissioned P. A. surgeon, from July 14, 1908.

Reed, E. U., commissioned P. A. surgeon, from Sept. 21, 1908.

Woods, E. L., commissioned P. A. surgeon, from Oct. 14, 1908.

Robertson, Gardner E., appointed acting asst.-surgeon, from Aug. 5, 1909.

Clark, G. F., orders of July 23, modified; ordered to duty at the Naval Hospital, Washington, D. C.

Robnett, A. H., commissioned P. A. surgeon, from March 24, 1909.

McDonald, P. E., P. A. surgeon, unexpired leave revolked; detached from the Naval Hospital, New York, N. Y., and ordered to the Naval Academy, Annapolis, Md.

Dean, F. W. S., detached from the *Maine* and ordered to the *Prairie*.

Seaman, W., P. A. surgeon, detached from the *Prairie* and ordered home to await orders.

Wilson, H. D., surgeon, detached from the *Kearsarge* and ordered to continue other duties.

McCormick, A. M. D., surgeon, detached from the *Maine* and ordered home to await orders.

Reed, E. U., P. A. surgeon, detached from the Naval Recruiting Station, Chattanooga, Tenn., and ordered to the Naval Recruiting Station, Nashville, Tenn.

Donelson, M., asst.-surgeon, detached from the Naval Recruiting Station, Oklahoma City, Okla., and ordered to the Naval Recruiting Station, Chattanooga, Tenn.

Public Health and Marine-Hospital Service

List of changes for the seven days ended Aug. 11, 1909.

Pettus, W. J., Asst. Surgeon-General, granted 27 days' leave of absence from August 16, 1909.

Gassaway, James M., surgeon, bureau order of July 20, 1909, amended to read on being relieved by P. A. Surgeon M. J. White, directed to proceed to San Francisco, and assume command.

Mead, F. W., surgeon, granted 1 month's leave of absence from Aug. 27, 1909.

McIntosh, W. P., surgeon, granted 21 days' leave of absence from Sept. 1, 1909.

Guiteras, G. M., surgeon, directed to proceed to Savannah Quarantine Station for temporary duty.

White, M. J., P. A. surgeon, directed to proceed to Philadelphia, Pa., and assume temporary charge pending arrival of Surgeon H. R. Carter.

Ramus, Carl, P. A. surgeon, on arrival of Asst.-Surgeon R. A. Herring, directed to proceed to Honolulu, Hawaii, and report to the chief quarantine officer for marine hospital duty.

Ramus, Carl, P. A. surgeon, granted 7 days' leave of absence *en route* to station.

Moore, Dunlop, P. A. surgeon, relieved from duty at Honolulu, Hawaii, and assigned to duty at Yokohama, Japan.

Trotter, F. E., P. A. surgeon, leave granted July 8, 1909, for 15 days from July 21, 1909, revoked.

de Valin, Hugh, asst.-surgeon, on the arrival of Surgeon G. M. Guiteras, directed to proceed to Stapleton, N. Y., and report to chairman of board of medical examiners to determine his fitness for promotion to the grade of Passed Assistant Surgeon.

Guthrie, M. C., asst.-surgeon, directed to proceed to Stapleton, N. Y., and report to chairman of board of medical examiners to determine his fitness for promotion to the grade of Passed Assistant Surgeon.

Atilles, Pedro del Valle, acting asst.-surgeon, granted 30 days' leave of absence from Sept. 1, 1909, with pay, and 15 days' leave from Oct. 1, 1909, without pay.

Duffy, Francis, acting asst.-surgeon, granted 6 days' leave of absence from Aug. 10, 1909.

Dynan, N. J., acting asst.-surgeon, granted 2 days' leave of absence from July 1, 1909, and 1 day, July 24, 1909, under paragraph 210, Service Regulations.

Goldsborough, B. W., acting asst.-surgeon, granted 3 days' leave of absence from July 31, 1909, without pay.

Harkin, F. McD., acting asst.-surgeon, granted 10 days' leave of absence from Aug. 10, 1909.

Rowles, J. A., acting asst.-surgeon, granted 25 days' leave of absence from Aug. 7, 1909.

Savage, W. L., acting asst.-surgeon, granted 30 days' leave of absence from Aug. 6, 1909.

Stevenson, J. W., acting asst.-surgeon, granted 12 days' leave of absence from Aug. 17, 1909, with pay, and a further period of 30 days' leave, without pay.

Thornton, M. J., acting asst.-surgeon, granted 4 days' leave of absence, July 8, 10, 11 and 12, 1909, under paragraph 210, Service Regulations.

BOARD CONVENED

Board of medical officers convened to meet at the marine hospital, Stapleton, N. Y., Aug. 30, 1909, for the examination of Asst.-Surgeons Hugh de Valin and M. C. Guthrie, to determine their fitness for promotion to the grade of Passed Assistant Surgeon. Detail for the board: Surgeon L. L. Williams, chairman; P. A. Surgeon John McMullen; P. A. Surgeon C. W. Vogel, recorder.

Health Reports

The following cases of and deaths from smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended August 13, 1909:

SMALLPOX—UNITED STATES

Illinois: Danville, July 25-Aug. 1, 2 cases; Moline, July 24-31, 1 case.
Indiana: Fort Wayne, June 19-26, 7 cases. July 3-10, 4 cases, July 17-31, 34 cases.
Kansas: Wichita, July 10-17, 1 case, July 24-31, 2 cases.
Kentucky: Lexington, July 10-17, 3 cases, July 24-31, 1 case; Newport, July 19-26, 1 case.
Michigan: Saginaw, July 24-31, 1 case.
Minnesota: Duluth, July 23-30, 4 cases
Missouri: St. Joseph, July 3-24, 15 cases.
Pennsylvania: Philadelphia, July 17-24, 3 cases.
Texas: Fort Worth, July 1-31, 1 case; San Antonio, July 24-31, 1 case.
Wisconsin: Appleton, July 17-31, 17 cases.

SMALLPOX—FOREIGN

Africa: Tripoli, June 19-July 10, 17 cases, 1 death..
China: Hongkong, May 29-June 19, 2 cases, 2 deaths; Tientsin, June 26-July 3, 1 case, 2 deaths.
France: Paris, June 26-July 10, 5 cases.
Indo-China: Saigon, June 19-26, 2 cases, 2 deaths.
Italy: General, July 11-18, 32 cases; Naples, 16 cases, 3 deaths.
Java: Batavia, June 16-July 3, 3 cases.
Portugal: Lisbon, July 17-24, 2 cases.
Russia: Moscow, June 26-July 10, 47 cases, 2 deaths; Odessa, July 3-17, 2 cases; Riga, July 10-17, 6 cases.
Spain: Barcelona, July 12-19, 4 deaths; Valencia, June 26-July 10, 12 cases, 1 death; Vigo, July 10-17, 1 death.
Turkey in Aisa: Mercine, vicinity, July 19, epidemic.
Turkey in Europe: Constantinople, July 4-11, 1 death.

YELLOW FEVER

Brazil: Manos, June 26-July 3, 1 death; Para, June 26-July 10, 12 cases, 12 deaths.

CHOLERA—FOREIGN

Indo-China: Saigon, June 12-26, 7 cases, 6 deaths.
Russia: General, July 17-23, 164 cases, 73 deaths; St. Petersburg, 526 cases, 234 deaths.

PLAGUE

Australia: New South Wales, Sydney, May 22-29, 2 cases, 1 death; Queensland, Mackay, June 6, 1 death.
China: Canton, June 12-26, 70 cases, 50 deaths; Hongkong, May 29-June 19, 33 cases, 32 deaths.
India: General, June 19-26, 628 cases, 531 deaths.
Indo-China: Saigon, June 12-26, 8 cases, 5 deaths.
Japan: Kobe, July 3-10, 2 cases, 1 death; Osaka, July 2, 1 case, 1 death.
Trinidad: June 19-July 3, 2 cases, 2 deaths, July 18, 1 case, 1 death.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Iowa: State House, Des Moines, September 21-23. Sec., Dr. Louis A. Thomas.

Missouri: Kansas City, September 20-22. Sec., Dr. J. A. B. Adcock, Warrensburg.

New York: Albany, September 21-24. Chief of Examinations Division, Charles F. Wheelock, Albany.

Massachusetts: State House, Boston, September 14-16. Sec., Dr. Edwin B. Harvey.

Colorado Requires Practical Examinations

Dr. S. D. VanMeter, secretary of the Colorado State Board of Medical Examiners, reports that practical tests are required by that board in the examinations for license to practice in Colorado. These practical tests are in (a) regional anatomy, making use of a living subject; (b) chemistry, particularly the making of a urinalysis; (c) pathology, consisting in the recognition of diseases by the examination of gross and microscopic specimens and (d) symptomatology, or physical diagnosis.

At least four state boards require practical tests in their examinations for license—Colorado, Massachusetts, Ohio and Minnesota. These practical tests form one of the best means of differentiating between graduates of a didactic or quiz-compend college and those who have received a thorough training in laboratory and clinic.

Nebraska State Board Controversy

The newly appointed board of secretaries of the Nebraska State Board of Health is as follows: President, C. P. Fall, M.D., Beatrice; vice-president, H. B. Cummings, M.D., Seward; treasurer, A. L. Muirhead, M.D., Omaha, and secretary, E. Arthur Carr, M.D., Lincoln.

The appointment of this board is being contested by the former board, it is reported, on the ground that, since the legislature repealed the wrong clause in the section of the act referring to the appointment of the state health inspector, and since this act also covers the appointment of the board of secretaries, the entire act was thereby made null and void.

The new board is, of course, the one recognized by the State Board of Health proper, which consists of the governor, the attorney general and the superintendent of public instruction. Mail addressed to the State Board of Health has been opened by the new board following the receipt of a favorable decision by P. V. Keyser, the acting assistant attorney general of the Postoffice Department at Washington. The whole matter will probably be tried in the courts within a short time.

New Officers of the Wisconsin Board

The newly elected officers of the Wisconsin State Board of Medical Examiners are: president, Dr. A. B. Bailey, Fennimore; secretary, Dr. John M. Beffel, Milwaukee.

Idaho April Report

Dr. W. F. Howard, secretary of the State Board of Medical Examiners, reports the written examination held at Boise, April 7-8, 1909. The number of subjects examined in was 11; total number of questions asked, 110; percentage required to pass, 75. The total number of candidates examined was 33, of whom 27 passed and 6 failed. The follov'ing colleges were represented:

College.	Year Grad.	Per Cent.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

Life Insurance Companies Working for Better Health Conditions

Following the announcement by Prof. J. Pease Norton of the Committee of One Hundred, that the Metropolitan Life Insurance Company of New York City is beginning a systematic campaign against tuberculosis among its policy holders, comes the announcement of the Provident Savings Life Assurance Society of New York that a bureau has been established in the medical department of the society to assist in guarding the health of policy holders and to be known as the Policy Holders' Health Bureau. The object of the bureau is to increase mortality savings by helping policy holders to prevent disease and to discover disease in time to check or cure it. This assistance is to be offered to policy holders without charge, through the medium of health bulletins, correspondence and free medical examination, at the expense of the company, every two years, of such policy holders as may desire it. After emphasizing the needless waste from illness among the general population, the president of the society states that it is not only the right but the duty of the society to use, within proper limits, the facilities at its command to protect the policy holders from needless suffering and loss of life, and that the results of such a work will soon return the relatively small cost of operating the bureau. It is proposed to issue health bulletins from time to time, giving the policy holders the benefit of recent discoveries and advances in medical knowledge, also to aid them in discovering symptoms of disease in time to effect a cure or to arrest its progress. The society will not, of course, undertake to provide medical treatment for policy holders, such services should be rendered by the local or family physician in each case, but will endeavor to discover disease in time to prevent serious results therefrom. To this end, periodical medical examination by the physicians of the society will be given every two years.

Professor Norton states that the inauguration by the great insurance companies of a general sanitary campaign, is in his judgment, the most important event in the history of life-insurance in fifty years. Obviously, the adoption of such a policy by a few of the insurance companies will eventually lead to its adoption by all, since the advantages to the policy holder of such a plan are apparent. It will only be necessary for the medical profession to demonstrate the material advantages of good health and the wastefulness of disease and sickness, to inaugurate an effective campaign against preventable disease.

British Medical Association Warns Prospective Medical Students

In a recent issue of the *British Medical Journal* containing the transactions of some of the branches of the British Medical Association, is an especially interesting circular, issued by the Salford Division and submitted to the council of the association with a view to securing its circulation in the public schools. The council as yet has taken no action on the matter, but transmits the circular to the representative meeting for consideration. The circular is of interest, as showing the economic conditions existing in the medical profession in Great Britain. After stating that the increase in the number of medical students in the last year shows the ignorance on the part of parents of the present economic crisis in the profession of medicine, the circular states:

"In general practice, to which nine-tenths of the entrants are destined, the field of work, and therefore the income, has been contracted and is bound to contract as disease becomes more and more preventable. A single instance of it: Dr. Davy, in his presidential address to the British Medical Association said: 'My predecessor told me that fifty years ago his average income from attendance on cases of typhoid was £300 ($1,500) a year. For the past few years my income from that source has hardly averaged five guineas.'"

The *British Medical Journal* says: "The average income of the practitioner has been estimated at from £200 to £250 a year. The chances of being able to save even to the extent of the capital expended in education are, in a large proportion of cases, slight, while reasonable provision for old age, after family expenses are met, is difficult and often impossible. This after a training lasting seven years and costing from £1,000 to £1,200 ($5,000 to $6,000), and even this pittance is only gained by working seven days a week and being on duty twenty-four hours a day, with the natural result that the death rate in the medical profession is higher than in any other, the army excepted.

"In France and Germany it has been found needful to issue letters of warning to intending students, as the results of practice are equally unsatisfactory there.

"We would, therefore, ask you to urge intending entrants to inquire further before joining so overcrowded a profession."

Marriages

HERMAN A. WHITE, M.D., to Miss Nellie Phelps, both of Clinton, Iowa, August 5.

ROBERT SLOAN IRWIN, M.D., to Miss Nora Elizabeth Hawver, both of Denver, July 14.

CALEB N. ATHEY, M.D., Baltimore, to Miss Helen Skipwith Wilmer, at Baltimore, August 2.

WALTER H. DARLING, M.D., Minneapolis, Minn., to Miss Florence Girard, of Boston, July 4.

JOSEPH E. POWLEY, M.D., to Miss Caroline Robertson, both of Altoona, Pa., at Philadelphia, July 29.

JOHN P. YOUNG, M.D., Richburg, S. C., to Miss Constance Witherspoon, of Lancaster, S. C., June 23.

LOIZA ELWELL, M.D., Battle Creek, Mich., and Philip Johnstone, of Belfast, Ireland, at Detroit, July 31.

WILLIAM E. SUNDERLAND, M.D., Estancia N. M., to Miss Hazel F. Rietz, of East Dubuque, Ill., at Santa Fe, N. M., August 4.

Deaths

Sarah Hackett Stevenson, M.D. Northwestern University Woman's Medical School, Chicago, 1874; a member of the American Medical Association till her enforced retirement through illness; who has been an inmate of St. Elizabeth's Hospital since 1906; died at that institution from paralysis, after an illness of three years, August 14, aged 64.

Dr. Stevenson was one of the first women in America to take up the study of medicine and to practice the profession, and had a hard fight in overcoming the early prejudices against her sex. As a club woman and philanthropist, Dr. Stevenson was well known; she was a member of many prominent women's clubs, among which were the Chicago Woman's Club and the Twentieth Century and Fortnightly clubs. She was instrumental in founding several well-known institutions, among them being the Chicago Maternity Hospital and Training School for Nursey Maids, and the Illinois Training School for Nurses.

At various times she had held important public positions, having been a member of the Illinois State Board of Health and professor of obstetrics at the Woman's Medical College, her alma mater. She had been attending gynecologist to Cook County Hospital; and was on the attending staffs of the Mary Thompson, Frances Willard and Maternity Hospitals.

Sarah Hackett Stevenson

Ignatius Donnelly, M.D. Jefferson Medical College, Philadelphia, 1883; formerly secretary of the Minnesota State Medical Society; a member of the staff of the City and County Hospital and St. Joseph's Hospital, St. Paul; a specialist on diseases of the nose, throat and ear; for many years a member of the American Medical Association; who went to Butte, Mont., two years ago to gain relief from heart disease, died July 31, in St. Mary's Hospital, Minneapolis, from heart disease. aged 51.

Matthew Turner Newton, M.D. Yale University, New Haven, Conn., 1851; in 1853 a member of the legislature from Salem, Conn.; assistant surgeon of the Third, and later surgeon of the Tenth Connecticut Volunteer Infantry during the Civil War; a member of the legislature from Suffield in 1893; president of the Suffield (Conn.) Savings Bank for twelve years; died at his home, July 24, from senile debility, aged 80.

Pliny Brett Morgan, M.D. Pulte Medical College, Cincinnati, 1881; of Berkeley, Cal.; a specialist on tuberculosis; and for many years professor of physical diagnosis and diseases of the lungs in Hahnemann Medical College, San Francisco; died at the home of his son in Ben Lomond, Cal., July 29, from heart disease, aged more than 70.

Jacob Moyer Hagesy, M.D. Rush Medical College, Chicago, 1862; for many years a member of the American Medical Association; once president of the Livingston County, Ill., Medical Society; a member of the American Public Health Association, died at his home in Mount Morris, N. Y., August 3, from cerebral hemorrhage, aged 76.

Erskine Boies Fullerton, M.D. Starling Medical College, Columbus, 1866; of Columbus, Ohio; a member of the American Medical Association; for many years professor of materia medica and therapeutics in Starling Medical College; died suddenly in the Good Samaritan Hospital, Portland, Ore., July 31, from cholera morbus, aged 66.

Francis Everard Roche, M.D. Queen's University, Dublin, Ireland, 1867; formerly surgeon major, British reserve military forces; a fellow of the Pathological Society, London; a member of the British Medical Association, and Utah State Medical Association; died at his home in Ogden, Utah, July 31, from septicemia, aged 67.

James A. Pinson, M.D. Medical College of Indiana, Indianapolis, 1872; an honorary member of the Vigo County (Ind.) Medical Society; a veteran of the Civil War; and a member of the local board of U. S. pension examining surgeons; died at his home in Terre Haute, June 22, from senile debility, aged 73.

George Mays, M.D. University of Pennsylvania, Philadelphia, 1861; a member and once president of the Philadelphia Medico-Legal Society; assistant surgeon and surgeon to the Ninety-third Pennsylvania Volunteer Infantry during the Civil War; died at his home in Philadelphia, August 1, aged 63.

Joseph W. Southall, Medical College of Virginia, Richmond, 1860; formerly superintendent of Public Instruction of Virginia; a Confederate veteran; for eight years a member of the state senate; died at his home near Jetersville, August 2, from cholera morbus, aged 77.

Cranston H. Dodd (license, Iowa, 1886); formerly postmaster of Koszta, Iowa, and coroner and justice of the peace of Iowa County; died in a hospital in Iowa City, August 2, from hemorrhage following an operation for pancreatic cyst, aged 62.

Roscoe Arthur Nash, M.D. State University of Iowa, Iowa City, 1894; formerly a member of the American Medical Association; for many years house surgeon at Mercy Hospital, Tipton; died at his home in Tipton, Iowa, August 1, from tuberculosis, aged 42.

Susanna Hayhurst, M.D. Woman's Medical College of Pennsylvania, Philadelphia, 1857; of Philadelphia; who had been connected with the Woman's Hospital of Philadelphia for thirty-three years, died in that institution, August 7, from senile debility, aged 89.

William C. Doane, M.D. Castleton (Vt.) Medical College, 1846; who held a position in the Department of the Interior, Washington, D. C., and was afterward inspector of prisoners during the Civil War; died at his home in Elmira, N. Y., August 2, aged 83.

Edward F. Menger, M.D. Medico-Chirurgical College of Philadelphia, 1884; a member of the Medical Society of the State of Pennsylvania; physician to the Old People's Home; died at his home in Philadelphia, August 3, from acute nephritis, aged 51.

Edward F. Paramore (registration, Wis., 1899); for fifty-three years an eclectic practitioner; a veteran of both the Mexican and Civil Wars; died at his home in Oconto, Wis., August 1, from paralysis, aged 78.

Samuel Joseph Patterson, M.D. Bellevue Hospital Medical College, New York City, 1867; of Dunlap, Iowa; died at the Methodist Hospital, Omaha, Neb., June 18, from postoperative pneumonia, aged 65.

Barnett P. Watts, M.D. College of Physicians and Surgeons, Keokuk, 1871; a member of the Illinois State Medical Society; died at his home in Randall (East Galesburg), Ill., July 31, aged 62.

Peter E. Jones, M.D. Medical Faculty of Queen's University, Kingston, Ont., 1866; formerly Indian agent of the Mississaugas of the New Credit, died at his home in Hagersville, Ont., June 29.

Joseph R. McLeod, M.D. College of Physicians and Surgeons, Keokuk, 1877; a pioneer practitioner of Findlay, Ohio; and a veteran of the Civil War; died at his home July 30, aged 75.

John H. Cox, M.D. Cincinnati College of Medicine and Surgery, 1854; a veteran of the Civil War; died at his home in Guthrie, Okla., July 8, from cerebral hemorrhage, aged 86.

Asher D. Atkinson, M.D. New York, 1840; one of the founders of the American Numismatic Society; died at his home in New Brunswick, N. J., June 26, aged 88.

Alfons Edler von Rosthorn, professor of gynecology and obstetrics at Vienna, where he succeeded Chrobak in 1907, died recently. He was one of the distinguished foreign guests at the Boston session of the American Medical Association in 1906, at which time a biographical sketch and a portrait were published in The Journal, May 5, 1906, pages 1372 and 1375. He delivered an address on "Uterine Cancer," and was made an honorary member of the Association. For the last seven years he has been associated with A. Martin in the publication of the *Monatsschrift für Geburtshülfe und Gynäkologie*. The second part of his important work on gynecology, in collaboration with Chrobak, which forms Vol. XX of Nothnagel's "System of Medicine," was published last year, the special subject being malformations of the female genital organs, classified from the etiologic standpoint. He was a contributor to many medical journals and wrote important chapters in Virt's "Handbook of Gynecology" and von Winckel's "Handbook of Obstetrics." His strong personality left a marked impression on his students and on all those brought in contact with him. He was born in Vienna in 1857 and had a professorship in turn at Prague, Graz and Heidelberg before he accepted the call to Vienna. He had many friends in this country and was the brother-in-law of Dr. C. S. Bacon of Chicago.

STATE MEDICAL SOCIETY OF WISCONSIN

Sixty-third Annual Meeting, held at Madison, June 30-July 2, 1909

(Concluded from page 480)

Cerebral Surgery

Dr. J. L. Yates, Milwaukee: Distinct emphasis should be laid on the underlying physiology, and a great many questions will arise in daily practice, such as apoplexy, meningeal hemorrhage in the new-born and cerebral tumor.

DISCUSSION

Dr. Arthur W. Rogers, Oconomowoc: It is disastrous to try to lower blood pressure in cases of intracranial tension. Cerebral hemorrhage is known to be amenable to treatment, but a decompression operation is often advisable. In regard to cerebral tumors: In diagnosis pay especial attention to headaches, vomiting and condition of the eye grounds, examining for choked disc, thus making early diagnosis.

Dr. N. M. Black, Milwaukee: In cases of suspected intracranial pressure, an immediate and prompt examination of the eye grounds by means of the ophthalmoscope and perimeter is important, and the earliest possible diagnosis should be made, so that surgical relief may be promptly given.

Address in Surgery: The Surgical Management of Handicapped Patients

Dr. George W. Crile, Cleveland, Ohio: Handicapped cases now largely constitute the mortality in surgical operations. Many patients with Graves' disease have been frightened to death. The psychic factor must be given special consideration. Cocain properly applied to nerve trunks affords absolute protection. The handicap of hemorrhage is now well under control by the use of direct transfusion of blood, injection of serum and special clamps. In the entire domain of medicine there is no subject so neglected, so badly done, with so much needless distress and disaster as the administration of anesthetics. The untrained anesthetist invites disaster. The administration of the anesthetic ranks close in importance to the work of the operating surgeon. Nitrous oxid with oxygen is excellent, especially in short operations, in which there is a strong contraindication to ether or chloroform. The shock is comparatively slight. The advantage of nitrous oxid over ether is greater when the handicap is in the central nervous system than when the handicap is in the heart. Scopolamin and morphin prior to gas anesthesia form an agreeable adjuvant; but gas with scopolamin and morphin should be reserved for certain handicapped patients, in whom it has been abundantly proved that this combination is distinctly safer and incidentally incomparable as to comfort. As an illustration, in patients with senile or diabetic handicap, use gas or oxygen anesthesia in amputations of lower limbs, cocainizing the sciatic nerve, and making a feather edge division of tissue. Similar careful work may render successful surgical treatment of cancer in the very aged, and when there is great hemorrhage transfusion of blood should be employed. We must enlist new and fundamental methods in these cases, and to accomplish this we require the use of greater facilities in the hospital, and a greater number of assistants, and the entire surgical resources of the hospital must be so mobile as to be concentrated at any moment on the fate of the patient. Surgery will then offer relief to a large number of patients who are now refused operation, or who, if operated on, succumb.

Experimental Investigation of Cancer

Dr. C. H. Bunting, Madison: This is one of the greatest problems in medicine. The scientific world has been criticized for directing its efforts rather to the cause than to the cure of cancer. But the criticism is scarcely deserved, as much work is being done in both directions. The causation of cancer is still unknown. Much has been expected from recent experimental methods, but as yet the results are disappointing. Cancer is pandemic, extending from the poles to the equator; although it is particularly a disease of the temperate zones. The negro is much less susceptible than the white race. France leads the world in percentage of cancer. Over 60 per cent. of cases occur in females. The greatest number of cases occur after 45, and the average age in the United States is 58. Hard labor out of doors gives susceptibility to cancer. More cases occur in small cities than in large. Wooded, hilly regions give undue proportion of cancer cases. Analysis of cases shows definite foci, groups of cases, cancer houses and cancer streets. It is a question whether or not cancer is really on the increase. The apparent increase is due to greater length of life, more exact diagnosis and closer statistics. Yet the first case of proved contagiousness of human cancer has yet to be reported. Chronic irritation is the most important predisposing if not actual cause of cancer. Note the frequency of cancer occurring in the scar of ulcer of the stomach, in the gall bladder following gallstones, and as the result of x-ray burns. Operation in this precancerous stage is often indicated as a preventive. Pathologic study as yet has disclosed no organism to be associated with cancer; there is no evidence that cancer is produced by a parasite. Those cells which become cancerous first show a degeneration of the protoplasm of the cell which causes a change in the nucleus. Jensen, in 1903, discovered that he could transmit cancer from one mouse to another by inoculation. The cancerous material which he thus produced in 1903 is still alive and growing in many of the cancer laboratories of the world. If any parasite existed it must be coextensive with the cell, because fragments of cells when inoculated on mice will not grow; but that a parasite should be of the same size exactly as the cell seems absurd. Cancer cells show great resistance to the action of the cold. The tumor cell of cancer is practically immortal. Artificial immunity to cancer has been produced in laboratories, in the lower animals. Jensen secured a serum from the rabbit which will cure cancer in mice. Dr. Crile has protected inoculated dogs by injecting the blood of immune dogs. It is along these lines of immunity that a cure for the disease is hoped for, but so far the work has been unsuccessful. It is interesting to note that the immunity once obtained renders the animal immune not only to the type of tumor injected, but to all types of malignant tumor, which again demonstrates that we are dealing not with a parasite, but with a biologic disease. The results experimentally have been unsatisfactory up to this point, but there is hope that we may yet find a cure for, even though we do not discover the cause of cancer.

Pompeian Surgical Instruments; with Exhibition of Instruments

Dr. L. F. Frank, Milwaukee, exhibited replicas of the collection of ancient surgical instruments taken from the ruins of Pompeii, including probes, spatulæ, curettes, traction and sharp hooks, perforaters, forceps, rectal specula, uterine trivalve and quadrivalve specula, trocars, cannulæ, phlebotomes, scissors, fixation forceps, epilating forceps, calculi extractors, male and female catheters and dilators. These instruments were beautifully made, usually of bronze, and were very similar to instruments designed for similar purposes and at present in use. While, however, the ancients performed Cesarean section, hysterectomy, laparotomy, lithotomy, nephrectomy and herniotomy, yet their surgery was, of course, largely confined to minor operations.

Report of the Recent Epidemic of Spinal Paralysis in Wisconsin

Dr. Jacolyn Manning, Eau Claire: A careful examination of all the facts at my disposal shows that anterior poliomylitis is a highly contagious disease, and that this particular epidemic was the result of an infection which journeyed along the main highways of travel from the Old World to the Eastern United States and thence to the Middle West.

DISCUSSION

Dr. C. M. Echols, Milwaukee: It is difficult to investigate this subject properly owing to the failure of physicians to report data. Little help can be secured from state boards of health in investigating this disease. They have statistics on mortality but not on morbidity. The etiology of the disease is doubtful. There is no symptom-complex by which we can make a diagnosis until after the damage is done. The disease is likely to attack children in perfect health and living under sanitary conditions as well as others. This is a crippling as well as a killing disease, from 50 to 60 per cent. of those attacked becoming permanently crippled.

DISCUSSION

Dr. C. A. Harper, Secretary State Board of Health: It is now a settled proposition that this is a disease of gastrointestinal origin. There seems to be a strong contagious element in the disease. Under present circumstances quarantine seems to be the only remedy.

Dr. L. W. Juergens, Portage: I would recommend the use of static electricity, what is called the wave current, instituted soon after the acute stage has been passed. Under this treatment patients usually recover the use of their paralyzed limbs.

Address in Medicine: Bearings of Occupational Conditions on Medicine

Dr. David L. Edsall, Philadelphia: We have a marvelous dearth of knowledge and great apathy shown in this country regarding these conditions, and an unhappy lack of regulation. This is to be contrasted with the activity shown in European countries and the excellent laws protecting the workingman in his occupations. I might cite an instance of one firm that makes an ingenious safety device and sells it, but it is not used in that firm's factory. Instances of this character should make the people of the United States bow their heads in shame, especially when we compare our disgraceful conditions with the excellence abroad. Physicians are the only persons with some scientific information who can observe the effect on public health of these conditions, and from whom the information should emanate which will lead to a betterment in the regulation of these occupational conditions.

Treatment of Syphilis

Dr. O. H. Foerster, Milwaukee: Mercury given for two or three years, combined with iodid during the third year, is still the accepted treatment of syphilis. The abortive treatment has proved a failure. Treatment should be instituted before the development of lesions in all cases in which the spirochaeta is found. Atoxyl is inferior to mercury in its control of symptoms and is not devoid of danger. Circumstances should determine the choice of the method of administration of mercury. Subcutaneous and intramuscular injections are finding favor. They are accurate and prompt, not entirely free from danger and possess the disadvantage of having to be repeated at short intervals. Two and one-half years' vigorous treatment of the disease is considered sufficient in this country to effect a cure. The Wassermann test is difficult of application and appears to stand in direct ratio to the length and vigor of treatment. It can not be said that at the present time the test is conclusive as a prognostic measure to determine a cure.

Treatment of Chronic Gonorrhea

Dr. E. A. Fletcher, Milwaukee: Gonorrhea untreated does not tend to recovery, but rather to progression. Many parents with chronic gonorrhea have exacerbations during treatment, but this does not prevent ultimate recovery, nor are such relapses indications for cessation of the treatment. Our purpose in treatment is not only to eliminate the gonococcus but also to restore the tissues to normal so far as possible. The discharge should be reduced to the minimum by daily irrigations. Injections and instillations are inferior to irrigations. Narrow meatuses are incised and suppurating ducts opened or cauterized. Infiltrations are treated by dilation. Medicated bougies are to be condemned, and ointments are usually of little service. When chronic prostatitis exists, massage of the seminal vesicles is advisable, followed by bladder irrigations and occasional posterior dilatation.

The Sociologic Aspect of the Venereal Diseases

Dr. P. F. Rogers, Milwaukee Over 90 per cent. of our young men stray from the paths of virtue before marriage; 60 per cent. contract venereal diseases which are difficult to cure. More wives than prostitutes have venereal diseases, innocently contracted from husbands; thousands of unborn babes are annually killed by prenatal infection; 60 per cent. of the blindness in the country is due to venereal disease. One-eighth of all cases in New York hospitals are venereal; 200,000 infected persons walk the streets of New York daily. These diseases burden society with incompetence. What are we going to do about it? The fundamental requirement is knowledge of how such diseases are acquired and transmitted. Teach the young boy and girl in the school, by a process of natural induction, by a slow evolution and unfolding of the subject, to know the truth about themselves and about the reproduction of the race, just as they are taught the mechanism of the fertilization, reproduction and development of flowers in botany. Let this instruction lead naturally at the age of puberty to a study of sexual physiology and hygiene; inculcate feelings of the highest respect and reverence for Nature's most wonderful secret, but let it no longer be a secret, to be hinted at, guessed at, giggled over and learned all distorted from contaminating sources. Teach the young man the manliness of self-restraint and virtue, and the falsity of the double standard of morality which condones in man what it condemns in woman, and at the same time teach him plainly the consequences of vice. Put innocent womanhood on its guard, and manhood on its honor to protect woman in the sacred relations of wedlock as carefully as she would be shielded from violence from without. Teach parents, by special lectures in the schools, to train their children as carefully in matters pertaining to sex as in deportment and religion; let mothers learn the wide difference between innocence and ignorance. Let physicians be diligent in disseminating the truth in season and out of season; and let pulpit and press break silence, lift the dense pall of ignorance, mystery and superstition that has rested so long on a subject that so vitally concerns society; let in the clear sunshine of intelligent enlightenment and truth, and we shall have a cleaner, purer, healthier and happier citizenship than the world has ever known.

DISCUSSION

President Gilbert E. Seaman, Milwaukee We should emphasize on every occasion the fact that gonorrhea is so frequently the cause of blindness. It has been estimated that from 25 to 33.3 per cent. of all cases of blindness are due to gonorrheal infection at the time of birth, and this infection can be absolutely prevented.

Dr. J. A. Bradfield, La Crosse: Whatever is done on this subject must come from the medical profession. I have been utterly disgusted with the teaching of our religious brethren on this subject, many of whom show woeful ignorance of its fundamental principles, on which it is their duty to be well posted. Religious teaching does not reach the root of the subject. Proper instruction in sexual physiology will do more toward the upbuilding of our nattion than anything else.

Detection of Tubercle Bacilli in the Blood

Drs. M. P. Ravenel and **Karl W. Smith**, Madison: About three months ago Rosenberger, of Jefferson Medical College, reported the finding of tubercle bacilli in the blood of patients in whom there were no signs or very slight signs of tuberculosis; and gave this out as a method of early diagnosis at a time when the disease would be readily curable. An examination of the blood of 18 tuberculous patients by this method, which is a very simple one, failed to demonstrate the tubercle bacillus in the blood in a single case. This investigation has been confirmed by reports from all over the world, and the only conclusion that can be reached is that the Rosenberger method is of no value.

Resection for Tuberculosis of the Hip Joint

Dr. H. Greenberg, Milwaukee: Cases suitable for resection are as follows: Cases of hip tuberculosis which, owing to mistaken diagnosis and hence, misdirected therapeutics have been allowed to progress until considerable destruction, abscess formation, and even mixed infection have occurred. There are other cases which despite early and correct diagnosis and diligent application of proper conservative treatment progressively go on with more destruction of tissue, abscess formation and grave constitutional symptoms. Another class of patients apparently yield to accepted therapeutics but continue from time to time to have renewed acute attacks, perhaps many years after the original one. In still another class the course is so rapid and virulent that nothing but radical procedure can save life or limb. When amyloid disease becomes evident or when extensive necrosis has occurred resection is especially indicated. In short, as soon as it becomes manifest that the recuperative powers of the patient are not sufficient to overcome the ravages of the disease, showing that a retrogressive process is going on, operation is positively indicated.

DISCUSSION

Dr. H. E. Dearholt, Milwaukee: Satisfactory results in the treatment of tuberculous joints do not depend so much on the technic of the operation as on the general hygienic conditions.

Other Papers Read

The following papers were also read: "Intravenous Therapy," by Dr. A. N. Baer, Milwaukee; "Neglect of the Sacroiliac Articulation by the General Practitioner," by Dr. Edward Evans, LaCrosse; "Treatment of Acute Gonorrhea," by Dr. D. J. Hayes, Milwaukee; "Vaginal Hysterectomy; A New Operative Technic to Establish a Sound Pelvic Floor and to Prevent Cystocele," by Dr. Ralph Elmergreen, Milwaukee; "The Physician and the Child," by Dr. L. R. Sleyster, Appleton; "Present Status of the Ocular Tuberculin Reaction," by Dr. S. G. Higgins, Milwaukee.

NEW JERSEY STATE MEDICAL SOCIETY

Annual Meeting held at Cape May, June 23-25, 1909

(Continued from page 477)

Indications for the Induction of Labor, Instrumental Delivery through the Vagina, and Cesarean Section

Dr. E. P. Davis, Philadelphia, said that the cases may be divided into those that have had the test of labor and those that have not. In patients who have not had the test of labor, labor should not be induced because of pelvic deformity. Whenever, by spontaneous efforts, the presenting part did not engage in the pelvis, the application of forceps was to be declined. An effort should be made to stimulate the patient's expulsive forces. If the parents place great value on the life of the child, labor should not be induced, because of the high fetal mortality; but if this is not the case, the best time for the induction of labor is at the thirty-fourth week. Delivery by abdominal section should be undertaken only when mother and child were in good condition, and no previous attempts to deliver had been made by forceps, version or any other means. When the mother was infected in long and impossible labor, delivery by Porro's operation offered the best chance for the mother. Occasionally, children, though badly bruised and injured by previous attempts at delivery, were saved by this operation.

Indications for Interference during Labor

Dr. Simon Marx, New York: In my opinion one gift that is possessed by very few obstetricians is the faculty of knowing both the how and the when for operative interference. I think that the operator should keep in mind the following: (1) The study of the woman before labor. (2) A positive appreciation of the position and presentation of the fetus and its relation to the pelvis. (3) The constant control of the fetal heart action and the maternal condition. (4) Interference only when there are positive indications which warrant such interference.

In estimating the safety of the unborn child the constant regularity of the heart beats is of undoubted value, while as regards the mother the pulse and temperature play a prominent part. Never interfere with labor save (1) when the mother shows symptoms of beginning exhaustion or (2) exhaustion of the fetus. To cope successfully with such an emergency as a sudden irregularity of the fetal pulse with a discharge of meconium from a woman whose os was hardly distended I doubt if one could operate quickly enough or deliver with such rapidity as to succeed without producing dangerous lesions. I think that when on examination a neurotic or spastic condition of the os is found with sharp edges, chloral should be given in divided doses up to three grams. In cases in which during the first stages there was danger of lagging pains and exhaustion, I frequently have found opium of good service.

DISCUSSION ON INDUCED LABOR

Dr. J. Watson Martindale, Camden, said that in women who have not had the test of previous labor, labor might go on without interference, even if there were considerable pelvic deformity. In those who had had the test of previous labor, he would unhesitatingly suggest the Cesarean section. Dr. Martindale said that there were more lacerations occurring in primiparæ than physicians usually think, as they often examine the skin perineum without inspecting the vagina. The number of lacerations in women delivered before his arrival was no greater than in those delivered when he was present. He had frequently felt the perineum tear while he was doing his best to prevent it. He described the technic of pubiotomy, and said that the indications were a true conjugate of three inches and a half, and possibly three and one-quarter. He did not agree with Dr. Marx that the subject of obstetrics is insufficiently taught in medical schools. On two occasions Dr. Martindale has found it necessary to induce labor on account of the uncontrollable vomiting in pregnancy. He had found calomel, in small, divided dose, of great benefit in threatened eclampsia. He thought that frequent examinations tended to produce sepsis, and that to apply the forceps before there was complete dilation of the os was likely to result in laceration of the cervix. On the other hand, it was possible to be too tardy in applying them. He said that the transverse diameter was materially increased by laying the woman on her back with her knee flexed on her thighs, and her thighs on her abdomen, and instructing her to pull on her knees. When a woman was suffering from severe labor pains and there was slow dilation of the os, he gave her enough morphin to deaden the pain.

Dr. Ellis W. Hodges, Plainfield, wondered whether methods for the quick delivery of women were not often intended more for the convenience of the operator than for the good of the patient, although he thought that one should interfere before the mother was so exhausted by the pain, shock, and fatigue that convalescence would be indefinitely prolonged. The nervous type of women, he said, often suffer with uterine inertia. The uterus plays out after a time, and he thought that in such cases the physician was warranted in bringing on labor. In case of an occipito-posterior presentation, he said, the only thing to do was to pull pretty hard. In case of rachitic dwarfs, nothing but Cesarean section should be attempted. If the diagnosis of placenta prævia is made early, he thought that labor should be brought on before the seventh month; but if the patient had gone to full term, one should at once plug the cervix and do Cesarean section. In cases of eclampsia, the uterus should be emptied at once. If the cervix were hard, this should be done by Cesarean section.

Dr. Edward J. Ill, Newark, did not approve of vaginal Cesarean section. He had seen, also, several cases of incurable vesicovaginal fistula due to high forceps delivery. He thought that the majority of patients with deep cervical tears remain invalids for the rest of their lives. In placenta prævia, when the bag of membrane could be felt anywhere in the vagina, it was not necessary to resort to prompt Cesarean section. If eclampsia came on in the seventh or eighth month, Cesarean section should be done; but not the vaginal Cesarean section, the results of which had been very disastrous.

Dr. Richard C. Morris, Philadelphia, thought that the importance of internal pelvimetry had been exaggerated; but he thought, also, that no physician had a right to attend a primipara without a knowledge of the size and shape of her pelvis, or to attend a multipara who had had a previous difficult delivery, without having studied the case from the standpoints of her previous labor and present physical condition. He said that it was impossible to learn these measurements accurately without the administration of an anesthetic. He made an appeal for a more general recognition of the value of induced labor, and said that the time would come when every woman with a conjugate diameter of four and a half centimeters, or less, would be submitted to Cesarean section. He had had great success in saving many patients from the major operation by means of induced labor, the practice of which also reduced the number of cases of forceps delivery and version. He agreed with the view that the forceps should not be applied to the unengaged head, as a general rule; but qualified this by saying that it should not be done unless one knew the pelvic diameter and the woman had been in labor pains for two or three hours. In a difficult forceps operation, the patient should be kept profoundly anesthetized during the third stage, and allowed to come out of ether just before the final delivery, the uterus then being strengthened by a dose of ergot. He did not think that quinin had any more effect than a glass of wine, acting as a general stimulant. In regard to placenta prævia, he said that he had yet to see a cervix so rigid and tight in a case of placenta prævia that had produced hemorrhage as not to permit him to pass the index finger readily through the cervix. He believed that in such cases Cesarean section had an exceedingly narrow field. In eclampsia, he thought that vaginal Cesarean section was not indicated in all cases. It should be performed in cases in which the condition came on without warning.

Dr. L. Davis said that if the test were made, it would probably be found that large numbers of lacerations occurred in both the anterior and the posterior segment. Failure to close lacerations in the anterior segment resulted in subsequent prolapse of the urethra, dystocia, and other minor troubles. If uterine inertia existed, it should be treated before delivering the patient. He was not in favor of giving ergot until the uterus had been emptied, but he approved of the use of strychnin. Section should be done in placenta prævia only when there had not been severe hemorrhage, when the child was viable, and when hospital facilities were at hand. Eclampsia tended to cure itself. He had not done vaginal Cesarean section, which he considered a dangerous operation. He considered the old treatment of placenta prævia satisfactory, if one did not care about the child. In taking the pelvic measurements, he thought it well to measure across the two processes of the ischia, and also the intertuberosity distance. He considered elective surgery the surgery of the future.

(To be continued)

AMERICAN ORTHOPEDIC ASSOCIATION

Twenty-Second Annual Meeting, held at Hartford, Conn., June 14-16, 1909

(Concluded from page 588)

Preliminary Study of the Mechanics of the Upright Position, With Especial Reference to Backache. (A Combined Orthopedic and Gynecologic Study)

Drs. R. W. Lovett and E. Reynolds, Boston, described a method for automatically determining the center of gravity of the individual in the upright position. The relation of the center of gravity to the hip joint, sacroiliac joints, feet, etc., they contended, determines the amount and character of back strain. They studied and formulated the effect of corsets and high-heeled shoes on the balance of the body and on the position of the center of gravity, and exhibited charts illustrating this.

DISCUSSION

Dr. A. Freiberg: What does displacement of the center of gravity mean? Has the proper method been adopted for correcting what is a pathologic state of affairs? I have heard nothing of what put the center of gravity forward. The logical thing to do is to go at the cause and correct it. I have not yet recovered sufficiently from my astonishment to swallow, with composure, those high heels and corsets which I see pictured on the wall.

Dr. Sayre: Undoubtedly many of our cases of backache are due to intrauterine and intrapelvic causes, and many of the pelvic abnormalities come from abnormal positions held on account of deficient muscular force. The chief use of a corset is to keep the bands of a woman's skirts from cutting into her, as a woman does not have her clothes hung from suspenders. I have had difficulty in getting corsets made loose enough over the iliac crests not to be uncomfortable when they are tight enough around the buttocks.

Dr. Wilson: Would similar conditions existing in a man be met by the application of some form of corset?

Dr. Lovett: We have simply presented a method that we believe is going to be of some use in elaborating the question of why the center of gravity is too far forward. We are sure that the corsets carry the center of gravity back and that high-heeled shoes also do this. In my practice I use corsets on men, just as in women, but less frequently, because one sees fewer backaches in men.

Dr. Reynolds: We must regard corsets as merely a temporary means of relieving the acute stage of static backache. In the cases that I have seen I have first relieved the cause in operating on the abdominal condition, and have used the corset to carry the patients beyond the backache, and then let them drop it. Bad corsets produce static backaches, and these can not be relieved so long as the bad corset is worn. We must learn to produce a good corset that is sightly and is near enough to the prevailing fashion to induce the patients to wear it.

Relation of Posture to Human Efficiency and Influence of Poise on the Support and Function of the Viscera

Dr. Joel E. Goldthwait, Boston: The human body is a delicately balanced organism, and no one part can be used with undue strain without straining other parts and wasting energy. In normal balance the muscles and ligaments are used without undue strain, and the movements are made with the minimum expenditure of energy. Not only is the correct balance of importance because of the effect upon the joints, bones, muscles and ligaments, but also because of the interference with visceral support and function that must take place if the poise is materially disturbed.

DISCUSSION

Dr. McKenzie: Unless we are to pander to a degenerate age we should not rectify postural defects by means of braces, but by training the physical organism so that it can maintain the ideal standard and attitude. While we want all the information that can come from mathematical study of the subject, it must be approached by the general study of the intuitive perception of the right attitude.

Dr. C. Riely: I have thought along the same lines regarding the circulation of the spinal cord as Dr. Goldthwait, and have talked over the subject with an anatomist and a neurologist. I had no doubt that it was the pressure of the muscles that caused the stagnation in the anterior and posterior vertebral columns, but thought it was an obstruction in cases of spine disease by the disease in the bodies of the vertebræ, as the veins that enter the bodies are very large.

DR. FREIBERG: How is Dr. Goldthwait going to take the patients from the tuberculosis clinic and give them the chance that other people have in the present state of civilization?

DR. J. E. GOLDTHWAIT: I do not believe it impossible to give them a chance. What has been done is no more remarkable than what can be done. When they use their bodies better they will have greater resistance and more power for work.

Congenital Deformities

DR. AUGUSTUS THORNDIKE, Boston, gave a short historical sketch of theories of causation, which to-day seem to be narrowed down to three: mechanical influence, heredity and maternal impressions. Further study, he said, is needed to reveal the true etiology and chronology of the inception of many skeletal deformities. Such studies must be of three kinds: studies of human embryos, of abortion sacs and of the embryos of certain lower animals.

DISCUSSION

DR. RUGH: I am not yet convinced that maternal impressions play no part in the production of congenital deformities. Recent investigation demonstrates the presence of nerve fibers in great number in the placenta and in the umbilical cord. This has gone a great way toward establishing the fact of a more intimate nerve relation between mother and child than had previously been suspected. I feel that in certain cases this acts as a factor in producing congenital deformities.

DR. MCKENZIE: I do not know what Dr. Thorndike meant by his statement that no case of congenital amputation of the limb very high up had been reported. I have seen lately a boy whose right arm had apparently been amputated just above the elbow.

DR. BAER: I should like to report another case almost identical with that of Dr. McKenzie, in which there was complete amputation just below the elbow.

DR. THORNDIKE: I think that Dr. Rugh is right. It was a surprise to me to find so little about maternal impressions in literature. As I have found cases of amputation high up so rare, I hope the gentlemen will report theirs fully with illustrations.

Bilateral Congenital Dislocation of the Head of the Radius; and Congenital Absence of the Acromion Process, Bilateral

DR. W. G. TURNER, Montreal, read these two papers. The first case presented a marked increase of the length of the radius as compared with the tibia, non-development of the coronoid fossa, and absence of the orbicular ligament. Strong silk was employed as an artificial orbicular ligament. He exhibited photographs and a radiograph of the second case, showing a condition not previously described.

DISCUSSION

DR. BLODGETT: Was there effusion between the head of the radius and the ulna? In that case one would expect to find a rotating condition of the rudimentary muscles.

DR. W. G. TURNER: There was no effusion between the radius and ulna. The upper end of the radius was perfectly movable. I operated on the left arm a year ago, with satisfactory result as to function; though the patient can not get the arm past the midway position.

Admissibility of Lay Testimony as to Mental Capacity

The Supreme Court of the Unitied States says, in the will case of Turner vs. American Security & Trust Company, that the rule governing the admission of the testimony of lay witnesses as to their opinion for or against the mental capacity of a testator, which has been prescribed by this court for the courts of the United States, is easy of statement and administration. Where the issue is whether a person is of sound or unsound mind, a lay witness who has had an adequate opportunity to observe the speech and other conduct of that person may, in addition to relating the significant instances of speech and conduct, testify to the opinion on the mental capacity formed at the time from such observation. In no other way than this can the full knowledge of an unprofessional witness with regard to the issue be placed before the jury, because ordinarily it is impossible for such a witness to give an adequate description of all the appearances which to him have indicated sanity or insanity.

Such testimony has been well described as a compendious mode of ascertaining the result of the actual observations of witnesses. Ordinarily, and perhaps necessarily, the witness, in testifying to his opportunities for observation and his actual observation, relates more or less fully the instances of his conversation or dealings with the person whose mental capacity is under consideration, and it is, of course, competent, either on direct or cross-examination, to elicit those instances in detail. The order of the evidence must be left to the discretion of the trial judge; but, when sufficient appears to convince the trial judge that the witness has had an opportunity for adequate observation of the person's mental capacity, and has actually observed it, then the judge may permit him to testify to his opinion.

This is not to say that, in a very clear case, an appellate court ought not to review the discretion of the trial judge. For instance, if it should appear that the witness had never spoken to the testator or seen any significant act, but merely observed him driving from day to day through the streets, and the opinion of such a witness as to sanity had been received, it would be the duty of the appellate court to correct the error. On the other hand, if the witness for years had been in constant communication with the testator, had frequently conversed with him and observed his conduct from day to day, the exclusion of the opinion of the witness ought to be corrected by the appellate court. These are instances of a plain abuse of judicial discretion.

Sufficiency of Testimony of Physician as to X-Ray Photograph

The Supreme Court of Iowa says, on the second appeal in the assault case of State vs. Matheson, that on the first appeal an exhibit, consisting of an x-ray photograph or radiograph which it was claimed showed the location of a bullet close to one of vertebræ was held to have been properly admitted in evidence, being identified by the electrician who made it as such a photograph. On the last trial the electrician who made the photograph was not called as a witness, and it was argued that the exhibit was improperly admitted. The court, however, thinks that there was no error in the ruling admitting the exhibit, for the physician who directed the taking of the photograph, and who was present when it was taken, testified that it was a correct representation of the condition of the subject's body at the time it was taken. This physician would know, as well as the man who operated the machine, that the radiograph was the result of the action of the x-ray machine in producing a representation of the bony structure of the body, and of any piece of metal, such as a bullet, which might be imbedded therein. Neither the operator nor the physician would be able to testify that the spot indicated on the radiograph was a bullet, but it would be competent for either of them to testify that the spot was such as a bullet imbedded in the body would produce. For the reasons just indicated, the testimony of the physician that the spot on the radiograph to which his attention was called represented a bullet in the body was also competent.

that convalescence would be indefinitely prolonged. The nervous type of women, he said, often suffer with uterine inertia. The uterus plays out after a time, and he thought that in such cases the physician was warranted in bringing on labor. In case of an occipito-posterior presentation, he said, the only thing to do was to pull pretty hard. In case of rachitic dwarfs, nothing but Cesarean section should be attempted. If the diagnosis of placenta prævia is made early, he thought that labor should be brought on before the seventh month; but if the patient had gone to full term, one should at once plug the cervix and do Cesarean section. In cases of eclampsia, the uterus should be emptied at once. If the cervix were hard, this should be done by Cesarean section.

Dr. Edward J. Ill, Newark, did not approve of vaginal Cesarean section. He had seen, also, several cases of incurable vesicovaginal fistula due to high forceps delivery. He thought that the majority of patients with deep cervical tears remain invalids for the rest of their lives. In placenta prævia, when the bag of membrane could be felt anywhere in the vagina, it was not necessary to resort to prompt Cesarean section. If eclampsia came on in the seventh or eighth month, Cesarean section should be done; but not the vaginal Cesarean section, the results of which had been very disastrous.

Dr. Richard C. Morris, Philadelphia, thought that the importance of internal pelvimetry had been exaggerated; but he thought, also, that no physician had a right to attend a primipara without a knowledge of the size and shape of her pelvis, or to attend a multipara who had had a previous difficult delivery, without having studied the case from the standpoints of her previous labor and present physical condition. He said that it was impossible to learn these measurements accurately without the administration of an anesthetic. He made an appeal for a more general recognition of the value of induced labor, and said that the time would come when every woman with a conjugate diameter of four and a half centimeters, or less, would be submitted to Cesarean section. He had had great success in saving many patients from the major operation by means of induced labor, the practice of which also reduced the number of cases of forceps delivery and version. He agreed with the view that the forceps should not be applied to the unengaged head, as a general rule; but qualified this by saying that it should not be done unless one knew the pelvic diameter and the woman had been in labor pains for two or three hours. In a difficult forceps operation, the patient should be kept profoundly anesthetized during the third stage, and allowed to come out of ether just before the final delivery, the uterus then being strengthened by a dose of ergot. He did not think that quinin had any more effect than a glass of wine, acting as a general stimulant. In regard to placenta prævia, he said that he had yet to see a cervix so rigid and tight in a case of placenta prævia that had produced hemorrhage as not to permit him to pass the index finger readily through the cervix. He believed that in such cases Cesarean section had an exceedingly narrow field. In eclampsia, he thought that vaginal Cesarean section was not indicated in all cases. It should be performed in cases in which the condition came on without warning.

Dr. L. Davis said that if the test were made, it would probably be found that large numbers of lacerations occurred in both the anterior and the posterior segment. Failure to close lacerations in the anterior segment resulted in subsequent prolapse of the urethra, dystocia, and other minor troubles. If uterine inertia existed, it should be treated before delivering the patient. He was not in favor of giving ergot until the uterus had been emptied, but he approved of the use of strychnin. Section should be done in placenta prævia only when there had not been severe hemorrhage, when the child was viable, and when hospital facilities were at hand. Eclampsia tended to cure itself. He had not done vaginal Cesarean section, which he considered a dangerous operation. He considered the old treatment of placenta prævia satisfactory, if one did not care about the child. In taking the pelvic measurements, he thought it well to measure across the two processes of the ischia, and also the intertuberosity distance. He considered elective surgery the surgery of the future.

(Concluded from page 588)

Preliminary Study of the Mechanics of the Upright Position, With Especial Reference to Backache. (A Combined Orthopedic and Gynecologic Study)

Drs. R. W. Lovett and E. Reynolds, Boston, described a method for automatically determining the center of gravity of the individual in the upright position. The relation of the center of gravity to the hip joint, sacroiliac joints, feet, etc., they contended, determines the amount and character of back-strain. They studied and formulated the effect of corsets and high-heeled shoes on the balance of the body and on the position of the center of gravity, and exhibited charts illustrating this.

DISCUSSION

Dr. A. Freiberg: What does displacement of the center of gravity mean? Has the proper method been adopted for correcting what is a pathologic state of affairs? I have heard nothing of what put the center of gravity forward. The logical thing to do is to go at the cause and correct it. I have not yet recovered sufficiently from my astonishment to swallow, with composure, those high heels and corsets which I see pictured on the wall.

Dr. Sayre: Undoubtedly many of our cases of backache are due to intrauterine and intrapelvic causes, and many of the pelvic abnormalities come from abnormal positions held on account of deficient muscular force. The chief use of a corset is to keep the bands of a woman's skirts from cutting into her, as a woman does not have her clothes hung from suspenders. I have had difficulty in getting corsets made loose enough over the iliac crests not to be uncomfortable when they are tight enough around the buttocks.

Dr. Wilson: Would similar conditions existing in a man be met by the application of some form of corset?

Dr. Lovett: We have simply presented a method that we believe is going to be of some use in elaborating the question of why the center of gravity is too far forward. We are sure that the corsets carry the center of gravity back and that high-heeled shoes also do this. In my practice I use corsets on men, just as in women, but less frequently, because one sees fewer backaches in men.

Dr. Reynolds: We must regard corsets as merely a temporary means of relieving the acute stage of static backache. In the cases that I have seen I have first relieved the cause in operating on the abdominal condition, and have used the corset to carry the patients beyond the backache, and then let them drop it. Bad corsets produce static backaches, and these can not be relieved so long as the bad corset is worn. We must learn to produce a good corset that is sightly and is near enough to the prevailing fashion to induce the patients to wear it.

Relation of Posture to Human Efficiency and Influence of Poise on the Support and Function of the Viscera

Dr. Joel E. Goldthwait, Boston: The human body is a delicately balanced organism, and no one part can be used with undue strain without straining other parts and wasting energy. In normal balance the muscles and ligaments are used without undue strain, and the movements are made with the minimum expenditure of energy. Not only is the correct balance of importance because of the effect upon the joints, bones, muscles and ligaments, but also because of the interference with visceral support and function that must take place if the poise is materially disturbed.

DISCUSSION

Dr. McKenzie: Unless we are to pander to a degenerate age we should not rectify postural defects by means of braces, but by training the physical organism so that it can maintain the ideal standard and attitude. While we want all the information that can come from mathematical study of the subject, it must be approached by the general study of the intuitive perception of the right attitude.

Dr. C. Riely: I have thought along the same lines regarding the circulation of the spinal cord as Dr. Goldthwait, and have talked over the subject with an anatomist and a neurologist. I had no doubt that it was the pressure of the muscles that caused the stagnation in the anterior and posterior vertebral columns, but thought it was an obstruction in cases of spine disease by the disease in the bodies of the vertebræ, as the veins that enter the bodies are very large.

Dr. Freiberg: How is Dr. Goldthwait going to take the patients from the tuberculosis clinic and give them the chance that other people have in the present state of civilization?

Dr. J. E. Goldthwait: I do not believe it impossible to give them a chance. What has been done is no more remarkable than what can be done. When they use their bodies better they will have greater resistance and more power for work.

Congenital Deformities

Dr. Augustus Thorndike, Boston, gave a short historical sketch of theories of causation, which to-day seem to be narrowed down to three: mechanical influence, heredity and maternal impressions. Further study, he said, is needed to reveal the true etiology and chronology of the inception of many skeletal deformities. Such studies must be of three kinds: studies of human embryos, of abortion sacs and of the embryos of certain lower animals.

DISCUSSION

Dr. Rugh: I am not yet convinced that maternal impressions play no part in the production of congenital deformities. Recent investigation demonstrates the presence of nerve fibers in great number in the placenta and in the umbilical cord. This has gone a great way toward establishing the fact of a more intimate nerve relation between mother and child than had previously been suspected. I feel that in certain cases this acts as a factor in producing congenital deformities.

Dr. McKenzie: I do not know what Dr. Thorndike meant by his statement that no case of congenital amputation of the limb very high up had been reported. I have seen lately a boy whose right arm had apparently been amputated just above the elbow.

Dr. Baer: I should like to report another case almost identical with that of Dr. McKenzie, in which there was complete amputation just below the elbow.

Dr. Thorndike: I think that Dr. Rugh is right. It was a surprise to me to find so little about maternal impressions in literature. As I have found cases of amputation high up so rare, I hope the gentlemen will report theirs fully with illustrations.

Bilateral Congenital Dislocation of the Head of the Radius; and Congenital Absence of the Acromion Process, Bilateral

Dr. W. G. Turner, Montreal, read these two papers. The first case presented a marked increase of the length of the radius as compared with the tibia, non-development of the coronoid fossa, and absence of the orbicular ligament. Strong silk was employed as an artificial orbicular ligament. He exhibited photographs and a radiograph of the second case, showing a condition not previously described.

DISCUSSION

Dr. Blodgett: Was there effusion between the head of the radius and the ulna? In that case one would expect to find a rotating condition of the rudimentary muscles.

Dr. W. G. Turner: There was no effusion between the radius and ulna. The upper end of the radius was perfectly movable. I operated on the left arm a year ago, with satisfactory result as to function; though the patient can not get the arm past the midway position.

1. **Who Are the Unfit?**—Woodruff claims that there is one form of unfitness which is causing dreadful disability wholly unnoticed—unfitness to climate when there is a migration to a climate markedly different from the ancestral one. Previous studies of the nervous and insane, he asserts, have shown that those most out of adjustment to this sunny climate, that is, the blonds, furnish a higher percentage of cases than they should, or than they do in cloudy places, like Scotland. The new studies of criminals and paupers show that the same factor is at work here too, among the myriad other causes of these unhappy types of human rejects. Similar studies among European criminals have not shown anything of this nature, because the populations are not migrants. Indeed, in Europe, it has always been customary to think of the criminal as brunette. In a visit to Clinton Prison, in New York State, where the worst classes of criminals are confined, and where he expected to see the place full of modern "black beards," Woodruff was astounded at the large number of blonds—some of them of very light type. It seemed as though the facts as to the brunetteness of criminals were the reverse of the popular idea on the subject. Of 279 white men whose eye color is mentioned, 144 had blue eyes, 40 gray, hazel and light brown, and only 95 dark shades of brown. The hair color of 253 was available for comparison and shows a general correspondence with the eye color. There were 19 with very light hair, 61 with light brown and brown, 61 dark brown, and only 112 black. The two extremes of very dark brunettes and very light blonds, such as the typical swarthy Italian and the yellow-haired Scandinavian, are in a decided minority, but the medium types tend strongly to blondness. It is safe to say, nevertheless, that blonds do not constitute anywhere near half of our population, which is notoriously brunette, with brown or gray eyes and dark hair in decided preponderance. The explanation of this local phenomenon is as follows: Criminologists are of the opinion that there is no criminal type, but that there is an instability of the nervous system or neurasthenia which is the basis of habitual crime. Hence, in America we find more nervous instability among the blond types and more of them drift into crime as a result. In many other ways, they prove their unfitness for these southern climates, notably an increased susceptibility to disease. Light affects the young far more than it does the parents. Hence blond adult immigrants may remain in fair health, but the deterioration begins in the next generation. Therefore we should not expect to find very many foreign-born among these blond criminals. The report of the superintendent of New York prisons shows that only 22 per cent. of the criminals in Clinton Prison are foreign-born and most of these foreigners are from brunette countries, like Italy, Poland and Russia. Very few come from blond countries, for only five were born in Scotland, one in Sweden, and none in Norway. The native-born, therefore, furnish the great majority of the blue-eyed professional criminals in New York.

3. **Ocular Tuberculin Reaction.**—The method of sterilizing the eye preparatory to using the tuberculin test as carried out by Hicks is as follows: For four days the patient's brow and face are washed with soap and water three times a day, and a 1/8000 solution of bichlorid of mercury is dropped into the eye after each washing. At the end of six days a culture is taken, just as in diphtheria, and incubated. If at the end of twenty-four hours or longer there are any colonies, the bichlorid solution is resumed for two days; then the eye is irrigated for two days more, twice a day, with physiologic saline solution to wash away the bichlorid and any organisms remaining. The next morning another culture is taken and incubated for twenty-four hours and cover slide preparations are made and examined, and if no organisms are found, the tuberculin test is made in the usual way. The eye after irrigation with saline solution is bandaged the afternoon before to keep foreign substances out. Hicks has failed to get any specific reaction in a number of cases when the test is applied in the above way, when without sterilization he has obtained the reaction in Bright's disease when there was no reason to suspect tuberculosis.

4. **Brain Tumor.**—Dale describes the case of a lad who suffered from brain tumor, but had none of the typical symptoms of cerebral compression. His symptoms indicated gastrointestinal irritation up to a few hours before death. The lad died of respiratory failure. The tumor was very small and was situated in the fourth ventricle, attached to its roof, to the right of the median line and directly over a point in the floor a little posterior to the center. It was an endothelioma.

8. **Ivy Poisoning.**—Baird has formulated the following treatment for ivy poisoning: (1) No scratching; (2) no ointments in the acute stage; (3) no bandages, for these tend to spread the poison to adjacent surfaces; if any protector is necessary, let it be a loosely applied dressing of absorbent cotton, kept moist at all times and changed at short intervals; (4) frequent and copious washings with lukewarm water and an unirritating soap; in handling the inflamed surface it is best to wear rubber gloves; (5) after the parts are washed, apply 2 to 4 per cent. warm solution of permanganate of potassium. This completely neutralizes any poison with which it comes in contact; the strength of the solution and the frequency of application are matters of judgment with the physician; (6) after the acute stage is past, ointments are permissible.

11 Superficial Dermatitis of the External Auditory Canal. C. J. Blake, Boston.
12 *Psychasthenia. A. H. Ring, Arlington Heights, Mass.

9. **Etiology of Tumors.**—Wolbach endeavors to present data which support the belief that the congenital tumors and tumors of infancy and early childhood most commonly take origin from isolated or misplaced cells. At least there is very positive evidence that certain tumors, such as the teratomata, hypernephromata, mixed tumors of the kidney and parotid and the retinal tumors arise from such errors of development. In the second part he endeavors to show that in the cases of *x*-ray carcinoma and a few other instances, such as bilharzia disease and Kangri carcinoma, there is a proved causal relationship between malignant tumors and antecedent pathologic processes. The more peculiar the source of the injury, the greater is the value of the evidence when the association is marked by a strikingly large number of cases. The similarity in the evolution of the skin carcinoma in widely different kinds of exposures points to a common underlying process whatever the nature of the injurious agent. In the cases of *x*-ray carcinoma and bilharzia carcinoma, there is a proved similar antecedent pathologic process. *X*-ray carcinoma is to be regarded as the first instance of an experimentally produced malignant tumor. Its occurrence following definite lesions of the skin, of a continuous and progressive character, places the whole subject of carcinomata following repeated injuries on a firm basis. It designates this field of investigation as the most promising one for research into the origin of carcinoma, because we have at least one and perhaps several examples of proved causal relationship.

The facts presented do not speak for belief in simple trauma as a cause for tumor production. They do indicate that long-continued progressive lesions of connective tissue supporting epithelium are responsible for the acquisition of malignant properties by the epithelium. Finally, it may be said that no series of experiments on animals, in the attempt to produce tumors, has ever been carried out which in any way approached duplication of those conditions found in man associated with the production of cancer. The element of time is, perhaps, the most important factor. Many years always elapse between the onset of the antecedent pathologic process and the occurrence of cancer. In the case of the *x*-ray, ten years is, perhaps, the shortest period.

12. **Psychasthenia.**—Ring believes that Janet, who coined the word "psychasthenia," intends to include under the term obsessions, manias of doubt, tics, agitations, phobias and the deliria of contact, states of anxiousness, neurasthenias and bizarre sensations of strangeness and depersonalization. These he would group together into a grand psychosis similar to hysteria and epilepsy. Psychasthenia, he says, is at base a disturbance of the feelings, the will and perception, and may range from mere eccentricities in the superficially normal through mild depression to melancholia and dementia. There are two types: (1) those in which the disturbance shows itself principally in motor fatigue, and (2) those in which the principal affection is in the sensory-motor and emotional sphere, the latter offering the less favorable prognosis. Phobias result from an unhealthy, prolonged feeling-tone of depressing ideas and may be conscious or subconscious. Doubts and indecision are evidence of fatigue of the higher centers which preside over formative and newly synthetized associations. The final judgment is thus rendered difficult or impossible and the victim finds himself in a state of vacillation and with a tendency to revert to the lower and simpler associations long formed. Weakened cerebral inhibition also plays its part. Obsessions and impulsions are the emotional result of the above factors and show themselves principally as a failure to inhibit the feeling-tone of ideas automatically repeated, yet the all-pervading asthenia checks the impulses short of accomplishment. Psychasthenia should be differentiated from hysteria, epilepsy, dementia præcox, manic-depressive insanity and paresis.

19 Tuberculous Infection through the Tonsil and Adenoid. J. A. Pratt, Aurora, Ill.
20 Nasal Tuberculosis Terminating in Tuberculous Meningitis. A. J. Hucy, New York.

13. **Bacteriology of Gonorrhea.**—Rathbun and Dexter claim as the result of clinical observation and investigation (1) that there are numerous cases of uncured gonorrhea which have no subjective symptoms or apparent objective symptoms other than those which can be determined by cultures made from secretions from the genitourinary tract; (2) that freedom from pus cells in the expressed smear from a prostatic secretion is by no means an evidence of cure of chronic prostatitis; nor is the presence of pus cells in a smear from the expressed secretion an indication of gonorrheal infection of that gland, nor is the presence of a Gram-negative diplococcus in the smear of this secretion a positive indication of the existence of gonorrhea of the prostate. At present we have no means at our disposal by which we can positively assure a patient that he is cured of gonorrheal prostatitis. Our best prospects of determining that fact lie along the line of perfecting methods of distinguishing the gonococcus from other organisms which so closely resemble it, and which may be accomplished by further experimental work with various culture media and proved by experimental inoculations. The authors found that the growth of the Gram-negative diplococcus on the blood serum which can not be transplanted to other media is strongly significant of the gonococcus, whereas Gram-positive diplococci, or Gram-negative diplococci growing on various other media, such as plain agar, potato, etc., are doubtful. The number of cases of uncured and incurable gonorrheal prostatitis is far in excess of what most clinicians are ready to believe.

14. Abstracted in The Journal, May 1, 1909, p. 1448.

15. **Achylia Gastrica and Insufficientia Pylori.**—Benedict attempts to show that there is such a condition as achylia gastrica and such a condition as insufficientia—or at least, relaxatio—pylori. They are absolutely different conditions, having in common only the element of depression of function, which may be functional in the ordinary sense or as secondary to an organic lesion. They are so different that there can be no question of correct nomenclature or interpretation of a single disease or symptom complex, so different that they may exist independently or may coincide in the same case. There is no characteristic, diagnostic, much less pathognomonic, symptomatology of either. The diagnosis must depend on actual investigation.

16. **Zymosia Gastrica and Tuberculosis.**—Knapp presents the results of the study of the gastric condition of 100 persons appearing at the New York Board of Health clinic for pulmonary tuberculosis. He found that each one of the 100 consecutive cases was one of zymosia gastrica. One patient showed zymosia gastrica many years before his pulmonary conditions developed. It would seem that this occurrence of sporulating, budding yeast is rather more than a mere coincidence, and that zymosia gastrica must bear a certain relation either to the development or to the progress of tuberculosis. Knapp assumes that zymosia gastrica may possibly be held responsible for the soil condition of tuberculosis and that it apparently constitutes some factor in the condition of tuberculosis.

46. **Palatopharyngeal Contractures.**—In Roe's case, the fauces were so extensively lacerated during an attempt to excise the tonsils, about four months before, that when healing had taken place there was a complete synechia or adhesion between the soft palate and the pharynx. There was complete occlusion of the posterior nares, except for a very small opening through which an ordinary small silver probe could

be passed. The adhesion was so thick and the tissues so infiltrated with inflammatory deposits, the result of the extensive inflammation that followed the operation, that the obtaining of a healed opening at each side through this thickened tissue proved to be practically out of the question. As it was necessary to cover but one surface of this opening, the upper or palatal side was most available. A rather broad flap was taken from the inside of the cheek near the lower jaw, including sufficient submucous connective tissue to assure the vitality of the flap. This was then brought down and the end turned backward and upward around the lower border of the soft palate, which had been sufficiently denuded of its mucous membrane around its lower border to secure union. This flap was then stitched at the sides and also through and through along the upper border of the end of the flap that had been turned up behind the palate.

Complete union of the flap took place, and on healing there was no undue contraction at the site of these flaps, nor was there the slightest inclination for a readherence of the soft palate to the pharynx at any point, all of which was very gratifying. The surfaces from which the flaps had been taken were speedily covered with mucous membrane and soon all traces of it disappeared. The central portion of the palate was thickened, and this thickened tissue was utilized by cutting and stitching it into shape so as to form a very desirable uvula. As the levator palati muscles had not been sufficiently injured to destroy their function, by the construction of this new uvula the function of the soft palate in closing the posterior nares during deglutination and phonation was almost completely restored.

58. **Treatment of Elephantiasis.**—Dr. Dubriel du Broglio, of the French colonial medical service, originated a treatment of elephantiasis consisting of the internal administration of 30 drops of tinctura ferri chloridi three times daily, in combination with bandaging of the affected limbs and complete rest in bed. Rossiter determined to make the experiment of administering the tinctura ferri chloridi without bandaging and permitting the patient to follow his usual mode of life. In every case so treated, the patient has shown decrease in the size of the affected part within a few weeks, and the effect on the fever is apparent even sooner. Rossiter therefore concludes, as a result of these experiments, that tinctura ferri chloridi has a marked effect on the elephantoid process, decreasing the size of the affected parts and restoring function to an even greater degree. Its most marked effect, however, is on the attacks of elephantoid fever, these attacks being markedly lessened in severity, the interval between attacks being greatly lengthened, and in several of the cases the attacks have apparently ceased. In one case of prolonged elephantoid fever with very marked chyluria of three weeks' duration, the chyluria disappeared entirely within sixty hours under the administration of tinctura ferri chloridi alone. So far as can be judged from the number of cases treated, elephantiasis appears to be arrested by this treatment if continued for six to twelve months, and if some method can be devised in conjunction therewith to dispose of the elephantoid tissue already formed, Rossiter believes that a cure may be looked for.

65. **Recurrent Nasal Hemorrhage.**—Spear's patient sustained a fracture of the left nasal bone, the vomer and mesethmoid. At the time of the injury there was considerable hemorrhage from both nostrils. The hemorrhage was controlled by packing. There was severe hemorrhage on a number of occasions afterward. The nature of the hemorrhage was peculiar; the bleeding was profuse while it lasted, and stopped apparently when the blood pressure lowered. Several careful examinations of the nasal cavity failed to reveal the source of the bleeding, but in all probability the bleeding point was situated in the right side of the mesethmoid region. The blood either came from a small artery that had been partially torn by the bone fragments or may have come from a damaged plexus.

There was no hemophilia in the boy's history or in the history of his family. As the case progressed and the boy lost more blood he become more anemic. His condition was critical and it was imperative to control the bleeding. Both facial arteries were tied without success. It was noticed that pressure over the right common carotid stopped the bleeding, so under cocain anesthesia the carotids on the right side were exposed; the external was ligated and a ligature was placed around the internal, but was not tied. This procedure controlled the hemorrhage for thirty hours, when it recurred, but to a much lesser degree. Finally, both nares were plugged with strips of gauze supported by Kyle's long nasal splints. This procedure controlled the hemorrhage. The following day these splints were removed; the bleeding again started, but was controlled by placing two long plugs made of twisted cotton soaked in a solution of boric acid; these plugs were placed in the right nasal chamber well back and upward, on the mesethmoid, and held in position by one long Kyle nasal splint. These plugs were left in place for forty-eight hours, the nasal cavity being kept fairly clean by dropping a little boric acid solution into and about the splint every two hours. The plugs were gently removed and replaced by others of a similar character, which were also left in position for forty-eight hours. These were replaced by one plug which was left in for twenty-four hours. No bleeding occurred after the introduction of the cotton plugs.

During the progress of the case gelatin was given in large quantities by the mouth, as was also calcium lactate and injections of 30 c.c. of rabbit's serum, all with the idea of increasing the coagulability of the blood.

66. **Traumatic Pneumonia.**—In Sterne's case, a man was struck on the left chest wall by a large coal bag while coaling ship. He reported fifteen or twenty minutes after the accident, complaining of severe pain at the seat of injury. Physical examination revealed nothing, except tenderness over the area of chest struck. There was no evidence of external injury other than redness and tenderness. No signs could be elicited which would point to fracture of a rib, nor was there any constitutional disturbance, other than pain on respiration. The injury was therefore treated as a contusion. At 7 p. m. the next day he again reported at the sick-bay complaining of some headache, accompanied by persistent pain in the chest, with some difficulty of respiration. Temperature was 104, pulse 96, and respiration 26. He was put to bed and showed no signs other than slight dulness on the left side from the second to the sixth rib in the nipple line. The treatment consisted in the administration of calomel, in broken doses, a sponge bath, and the application of an ice cap.

On the morning of the second day he had a rather severe nasal hemorrhage, temperature had dropped to 100.5, pulse to 84, and respiration to 22. A painful cough developed, dry in character so that no sputum was available. Magnesium sulphate was administered in dose of 1 ounce with good result. The ice cap was continued and he was given two sponge baths during the day. At 1 p.m. his temperature was again 104, the pulse 96, and respiration 24. Physical signs were still negative. All through this case the physical signs were negative, but the temperature, pulse and character and frequency of the respiration with the rusty sputum were sufficient to make the diagnosis. The element of trauma is interesting, as it is a rare cause of pneumonia, and in this case was evidently directly responsible for the disease in view of the fact that the patient was previously perfectly well and had no history of exposure or any of the other well-known predisposing factors in the etiology of pneumonia.

81. **Hyperalgesia of the Skin in Pulmonary Tuberculosis.**—White and Van Norman have observed that hyperalgesia of the skin to pain, heat and cold sensations is present over active tuberculous involvement of the lungs. It has a very definite distribution, corresponding very closely to the limits of active involvement in the lungs. With the arrest of activity hyperalgesia disappears. Hyperalgesia depends on involvement of the lung and not of the pleura.

82. **Uncinariasis Among Southern-Bred Soldiers.**—Chamberlain says that infection with uncinaria is very common among southern-bred soldiers during the first three years of service. In 100 men examined, 60 per cent. showed uncinariasis. Among new recruits the percentage of infections is at times as high as 85. Southern-bred soldiers with more than three years' service show a much lower percentage of infection, only 11 per cent. in 33 cases. The worms gradually die out, most of them during the first three years, and under the favorable sanitary conditions obtaining in the army at home reinfection occurs rarely, if at all. The symptoms produced by a light infection with hookworms are so slight that they can not be detected by the usual methods employed by the examining surgeon and the diagnosis must be made with the microscope. An eosinophile count of over 5 per cent. is strong evidence of infection with an intestinal parasite, but one below 5 per cent. is no evidence against uncinariasis.

The parasite in probably all cases is *Necator americanus*. In some cases, the worm probably lives several years in the intestines. In many light infections the ova are difficult to find, requiring the complete examination of five or six cover-glass preparations. Farm life is very important as a predisposing cause. Among 74 men who had farmed at some time, 81 per cent. were infected. Most of the men had gone barefooted in childhood, and over half reported having had ground itch, though usually not since childhood. Southern recruits are less well-developed physically than northern ones. Uncinariasis in childhood is a probable cause of this underdevelopment. Light infections do not materially affect the efficiency of the soldier, though the majority of men report that they feel more vigorous after treatment. Treatment of the light infections is of great importance in any attempt to stamp out the disease.

83. **Disseminated Miliary Tuberculosis of Skin.**—Tileston calls attention to the occurrence in infantile miliary tuberculosis of a skin eruption, which consists of scattered discrete papules, which at the beginning are the size of pin-heads, and are soon capped by tiny vesicles with cloudy or purulent contents. Later on, the vesicle ruptures or dries up, and its place is taken by a crust. It is this stage which is most characteristic. The lesion is then from 2 to 3 millimeters in diameter; that is to say, about the size of a rose spot in typhoid fever, and consists of a flat papule, only slightly elevated, of a dull red color, often glistening. The center is occupied by a crust, on the removal of which there is disclosed a minute but sharply defined dell or hollow, varying in size from the point to the head of a pin. Healing takes place in case the child lives long enough, leaving a tiny white scar surrounded by a halo of brownish pigmentation. The duration of the individual lesion varies from one to several weeks. The spots appear in crops, so that all the different stages may be present at the same time. Rarely a vesicular type of eruption is seen, with vesicles up to the size of a small pea, surrounded by a slightly elevated area of redness and infiltration. This form likewise shows, when in the crusting stage, the characteristic hollow in the center.

The distribution is fairly constant, the majority of the spots being situated on the buttocks, genitalia and adjacent portions of the thighs; *i. e.*, on the parts covered by the diaper. This is probably due to irritation by the feces and urine, with consequent lowered resistance of the skin. The abdomen, front of the chest, thighs and legs, and sometimes the arms, face neck, palms and soles may show a few spots; the back is usually free, except the buttocks. The eruption is not, as a rule, symmetrical and is seldom profuse, the total number of spots usually not exceding from twenty to thirty, while often only half a dozen are present. They never become confluent.

Out of 32 cases of tuberculosis in children, in the first three years of life, examined by Tileston, 7, or 21 per cent., have shown the eruption. In view of the fact that most of the children were seen only once or twice, the real proportion must be considerably higher. The list includes cases of tuberculosis of the bones, lymph nodes, lungs, intestines, meninges and peritoneum. All the children with spots who came to autopsy were found to have miliary tuberculosis. It is by no means unlikely, however, that a few spots may appear on the skin in cases with localized tuberculosis, as occurs in older children and adults. In general, the chronic cases are more apt to show spots, while in the acute ones the patients probably die before the eruption has time to develop. Thus out of fourteen patients with tuberculous meningitis, only one had spots. Two hundred children suffering from various diseases, other than tuberculosis, failed to show any eruption resembling the one under consideration.

The cause of the eruption is the tubercle bacillus. In 70 per cent. of the cases, tubercle bacilli were demonstrated within the skin lesions, sometimes in large numbers. In others the bacilli were so scanty that they were found only after a prolonged search. The association with miliary tuberculosis and the presence of tubercle bacilli in the capillaries leave little doubt as to the mode of origin of the process; it is embolic, analogous to the formation of rose spots in typhoid and to the pustular efflorescence of staphylococcus septicemia.

86. **Modification of Sahli Butyrometric Test Meal.**—The method proposed by Friedman, for the study of the gastric functions is a modification of the Sahli test meal, consisting of one-third condensed milk and two-thirds water, the object being to obtain a stable emulsion of fat. With a very little extra work one can calculate the amount of gastric juice in

the stomach at the time of aspiration, and so determine its real acidity as well as the gastric motility, etc. This yields definite standards for comparison, which enables one to make a more accurate functional diagnosis than is at present possible otherwise. Among the advantages of this meal over the Ewald and Riegel meals is the consideration that the conditions of most of the gastric functions may be determined by a single aspiration. Its advantages over the Sahli meal are its constancy of composition, the ease with which it may be prepared and administered, its strong secretory stimulating powers, and the stability of the emulsion.

124. **Operative Procedures for Relief of Dystocia.**—Miller believes that in a perfectly healthy individual in whom there is no evidence of toxemia, it is justifiable to make an attempt to prevent the overgrowth of the child. In properly selected cases induced labor is less dangerous for the mother, carrying with it a lower mortality than either pubiotomy or Cesarean section. The induction of premature labor is probably the choice of procedures in cases in which the delivery can readily be accomplished at the thirty-sixth week or beyond, and in some instances might be indicated a week or more prior to this time. The proper time for interference should be determined by the Stone method of measuring the fetal head while still in the uterus, by careful pelvic measurements, and by repeated bimanual examinations by Mueller's method. It is extremely important to provide skilled care for the premature infant for at least two months after delivery, and the most essential part of this skilled care is that the child be breast-fed, by either the mother or a wet nurse. The method of delivery in any individual case should be determined before labor actually starts, as the maternal mortality comes largely from operations having been done when delivery by the natural forces supplemented by forceps operation have failed. Miller *can not conceive of any condition in which craniotomy* on the living child is justifiable.

125. **Carcinoma of Lower Lip.**—Hertzler advocates the removal of the glands and the gland-bearing tissue adjacent to the lip, in all cases, including the very early ones. The gland-bearing area would be the submental and the inframaxillary in the first link, and the subhyoid and the submaxillary in the second link, and finally, the deep cervical in the third. Hertzler believes that the first and second links should be removed in all instances. If these are not obviously involved, their removal, together with the gland-bearing tisssue in this region, is all that is required. Should they be obviously cancerous, then the third link, the deep cervical glands, on the corresponding side, or both sides, should also be removed.

The removal of this amount of tissue can best be made by an incision passing over either side of the point of the chin, curving over the inferior maxillary bone, extending back to the anterior border of the masseter muscle, hence downward to the point of crossing of the omohyoid and the sternomastoid muscles. The incisions pass on either side of the point of the chin. The object of this is to leave the skin attached at this point, for if the skin at this point is loosened it is difficult to keep the flaps in position over the point of the chin. When the lesion is extensive this point of attachment can not, of course, be preserved. The lymphatics pass on either side of this tissue and there is no reason for its removal. The submental space may easily be cleaned out by pulling the skin to either side. The character of the incision in the lip itself depends on the size of the lesion. As in the breast, the dissection should be begun at the point farthest from the growth and proceeded with toward the lesion. The dissection should begin, therefore, at the angle between the omohyoid and sternomastoid muscles. When the dissection is completed up to the chin, the tumor should be thoroughly cauterized before beginning the operation and protected by a wet formalin pack. The incision in the neck can be conveniently closed with a running suture of silk or catgut. Drainage should be provided for at the lower angle of the wound. For the closure of the incision in the border of the lip Hertzler has adopted a special plan. It is a double loop suture. The advantage of this suture is that the vermilion border is held in apposition, while the knots are all placed on the skin surface of the lip, where they cause no irritation.

126. **Herniotomy without Buried Sutures.**—Prince describes his method as follows: Make an incision one and a half inches above Poupart's ligament down to the fascia of the external oblique, freeing the anterior or external surface of this fascia from fat, etc. Then locate the external ring by stripping

covered. Then make the incision through the external oblique on a grooved director passed into the external ring, or without the use of the director, as one prefers. This incision should be so made that the reflected portion of the external oblique above Poupart's ligament will be sufficient to cover the cord. The sac is dealt with in the usual way. The fascia of the external oblique is then dissected from the internal oblique muscle until its edge can be easily brought down to the edge of the internal oblique and transversalis muscles. Both ends of a suture of strong silkworm gut are threaded on a needle. Each needle is passed through the transversalis and internal oblique muscles, both emerging through fascia of the external oblique. Both needles are now passed under the cord. One needle is passed below, the other above Poupart's ligament to the skin surface. These sutures are then tied over a piece of rubber tubing or roll of gauze, which brings the two muscles and fascia of the external oblique in contact with Poupart's ligament. This transplants the cord on top of the fascia of the external oblique. Then make a slit in the fascia of the external oblique to receive the reflected portion of the fascia, which is turned back to expose Poupart's ligament. This reflected portion of external oblique fascia is then pulled into the slit and acts as a covering of the cord. When these sutures are tied the wound is completely closed. The sutures may be made to come out above the wound and tied over a roll of gauze, as the deep sutures, and the wound is then closed by a subcuticular suture. The stitches are usually left in for twelve days. It is essential to have a good quality of silkworm gut.

138. **Progressive Pernicious Anemia.**—Witherspoon urges that in all cases of pernicious anemia there should be a thorough examination of the stools, special care being used in seeking for the *Bacillus capsulatus aërogenes*. When this bacillus or the percentage of anaerobic bacteria found in evacuations from bowels is large, then after thorough trial at colonic irrigation, and failure to improve symptoms or to lessen the percentage of bacteria, the operation of appendicostomy is warranted.

16 Rigor Mortis in a Stillborn Child. C. Eglington.

1. **Treatment of Disease.**—Osler says that the student should follow most carefully the action of those drugs the pharmacology of which he has worked out in the laboratory. He should be sent out from the hospital knowing thoroughly how to administer ether and chloroform. He should know how to handle the various preparations of opium. Each ward should have its little case with the various preparations of the ten or twelve great drugs, and when the teacher talks about them he should be able to show the preparations. He should study with special care the action of digitalis on the circulation in cases of heart disease. He should know its literature. It should be taken as the typical drug for the study of the history of therapeutics. He should day after day personally give a syphilitic baby inunctions of mercury; he should give deep injections of calomel, and he should learn the history of the drug from Paracelsus to Fournier. He should know everything relating to the iodids and the bromids, and should present definite reports on cases in which he has used them. He must know the use of the important purgatives, and he should have a thorough acquaintance with all forms of enemata. He should know cinchona historically, its derivatives chemically and its action practically. He should study the action of the nitrites with the blood-pressure apparatus, and he should over and over again have tested for himself the action, or the absence of action, of strychnin, alcohol and other drugs supposed to have a stimulating action on the heart and blood vessels.

5. **Wassermann Reaction in General Paralysis of Insane.**—Smith and Candler examined a series of spinal fluids from cases of general paralysis and other diseases. The method employed was essentially that of Wassermann. They used ox blood corpuscles instead of sheep's. They examined 175 samples of cerebrospinal fluid, derived from 127 individuals. Of these 127, 64 were cases of general paralysis, and in 59, or 92.1 per cent., a positive result was obtained, while in 5, or 7.8 per cent., the reaction was negative. These 64 cases include 7 from which the fluid was obtained only after death, and all of these gave positive results. It might be objected that the examination of such postmortem fluids could give no trustworthy results. In the case of cerebrospinal fluids, however (whatever may be the case with serums), this is not so. If the fluid is withdrawn within twenty-four hours after death from a body which has lain in the cold room during the in-

terval (as was done in all the authors' postmortem cases), the Wassermann reaction is not altered. Examinations were made of such fluids from over 30 control cases, with no positive results. The spinal fluid even of a general paralytic, which had been negative during life, remained so after death. Of 21 cases undoubtedly in the most advanced stages of the disease, over 90 per cent. gave the reaction, while of 16 cases, certainly in a middle stage, only 81 per cent. were positive. They also examined 9 cases (not included above), in which the definite diagnosis could not be made clinically, though it was considered possible that general paralysis might develop. These all gave negative results. Fluids from 63 cases in which the patients were not suffering from general paralysis were examined, in 32 of which the fluid was obtained during life. In no single instance was a positive reaction obtained. These cases included melancholia (9); senile mania (10); epilepsy (2); cerebral tumor (2); cerebellar tumor; syphilitic meningitis; lues cerebri; tuberculous meningitis; alcoholism (3); disseminated sclerosis; dementia præcox; posthemorrhagic and other softenings; and a few fluids received for diagnosis of tuberculous or epidemic meningitis.

In suspected general paralysis the authors claim that a positive Wassermann reaction with the cerebrospinal fluid is practically diagnostic. In only two other conditions is it ever obtained, namely, in tabes and in syphilis located in the central nervous system of the meninges. In tabes it occurs regularly, but with much less frequency than in general paralysis.

28 Spasmodic Torticollis Following Chorea. T. E. Lister.

17. **Early Operation in Acute Appendicitis.**—Turner says that if acute cases are treated by early operation, when once the condition is clearly diagnosed, the mortality of such early operations, although done during the attacks, should not be, and will not be much, if at all, greater than of those done between attacks. He attributes the present mortality of operations during attacks almost entirely to delay.

June, X, No. 6, pp. 353-416

29 *Decortication and Thiersch Flaps to Remove Traces of Tattooing. (Détatouage par décortication.) W. Dubreuilh.

29. **Removal of Tattooing.**—Dubreuilh relates two cases in which he relieved men of disfiguring tattooing by shaving off the superficial layer of the derma. It is not necessary to cut deep, but merely peel the surface. Thiersch flaps applied on this healthy raw surface take hold and grow with remarkable facility. The superficial layer is sliced off with a razor; no grafts are required on regions abounding in hair and sebaceous glands, like the face and nose. The skin heals over without a scar or retraction.

30 *Kala Azar in Children. (Le kala azar infantile.) C. Nicolle. Commenced in No. 5.
31 *Serodiagnosis of Hydatid Cyst Disease. (Séro-diagnostic de l'échinococcose.) Weinberg.
32 Methods of Staining Common to Actinobacillosis, Actinomycosis and Botryomycosis. P. Chaussé.

30. **Kala Azar in Children Near the Mediterranean.**—Nicolle states that twelve cases have been reported of a special infection affecting exclusively children under the age of 6, and encountered to date only in Tunis and southern Italy. The symptoms include pallor, emaciation, enlargement of spleen and liver, fleeting, painless edemas and extremely irregular temperature presenting several maxima during the course of the day, uninfluenced by quinin. A tendency to hemorrhages and purpura is also frequent. The infection runs a long chronic course, and in all the cases differentiated during life the disease proved fatal. The parasite seems to be identical with that of kala azar in India, except that it attacks only children. In three other children now in good health a retrospective diagnosis of the infection has been made, and these cases demonstrate that the little patients may sometimes recover. His research on animals has shown that "infantile kala azar" is a natural infection of the dog. The parasite was found in 4 out of 222 dogs examined at Tunis, but the infection in dogs does not induce as characteristic a syndrome as in children.

31. **Seroreaction in Hydatid Cyst Disease.**—Weinberg reports from Metchnikoff's laboratory at Paris 52 cases in which the diagnosis was confirmed by the findings of the complement fixation test. The blood was found to contain specific antibodies against echinococci; in 26 of the 27 cases with positive findings the operation revealed the parasites. In one case with negative findings the operation revealed a hydatid cyst and the test, twenty days later, induced a positive reaction. The test in hydatid cyst disease seems to be even more constantly positive than the similar test for syphilis, and it is proving an important aid in the clinic. In one case the clinical signs suggested hydatid cyst, confirmed by the pronounced eosinophilia of 7.5 per cent., but the test applied on three occasions gave constantly negative findings. The stools were then examined and quantities of eggs of the trichocephalus were discovered, explaining the eosinophilia, and the operation revealed merely gall-bladder inflammation. In other cases with negative findings in both stools and serum, the supposed hydatid cyst proved to be a hemorrhagic cyst in the pancreas, or abscess in the bile duct. In one case with 10 per cent. eosinophilia the test was negative and the liver hard, but certain findings in the serum were similar to those that had been noted with cancer of the liver, and this proved to be the trouble in this case. In all the other negative cases the test added another element to sustain the dubious diagnosis of some other affection. Examination of 26 other patients who had been operated on for hydatid cysts years before showed the persistence of antibodies in a large proportion, and it was found that in all these positive cases the cyst had been opened, while in the negative it had been removed unopened.

June 29, LXXIII, No. 26, pp. 689-720

38 *Diagnostic Importance of Antitryptic Power of Blood Serum (Pouvoir antitryptique du sérum sanguin et sa valeur diagnostique.) F. Widal and S. de Poggenpohl.
39 *Dysenteric Liver Abscess. (Abcès du foie dysentérique nostras.) E. Boinet.

38. **Diagnostic Importance of Antitryptic Power of Blood Serum.**—Widal obtained positive results in 13 out of 14 cases of cancer even when there was no cachexia, as in one case of epithelioma of the upper lip in which the antitryptic index was 1 to 7. In the one negative case the test was made on a moribund patient. In 8 cases suspected of cancer the reaction was negative, and the course of the cases confirmed these findings, the affection proving to be a cyst in the pancreas, tuberculous pleurisy, chronic mammitis, gumma of the lip, nervous spasm of the esophagus or gastric ulcer. This makes 176

cases on record in which this test has been applied, with positive findings in 91.4 per cent. In 64 other chronic affections—lobar pneumonia, typhoid fever, tuberculosis or nephritis—the reaction was positive in 11 per cent. The high antitryptic index in the 3 cases of typhoid fever may have been connected with the complications observed in these cases.

39. **Dysenteric Abscess of the Liver.**—Boinet describes twenty-one cases of abscess in the liver in France presenting the same characteristics as a tropical abscess. It may follow a mild dysentery which may not have attracted attention, and it may run a latent course simulating a tuberculous process in the lungs, pneumonia, pleurisy or a suppurative hydatid cyst. In acute suppurative hepatitis with multiple abscesses, or an abscess with necrosis, the general symptoms may suggest typhoid fever or severe jaundice and the actual abscess be overlooked. The principal complications of these bacillary liver abscesses are adhesion between the focus or foci and the colon; perforation into the air passages or pleura; pus collecting below the diaphragm, multiple abscesses in the left lobe of the liver, and postoperative bile fistula.

44 *Congestive Edema at Apex Simulating Tuberculosis. (De quelques congestions-œdèmes pulmonaires localisées aux sommets des poumons simulant la tuberculose, et de quelques congestions pulmonaires péritüberculeuses.) G. Caussade and P. Queste.
45 Ascarides Simulating Gastric Ulcer. (Ascaridiose intestinale ayant simulé un ulcère de l'estomac.) R. Gaultier.

44. **Edematous Congestions at Apex Simulating Tuberculous Process.**—The edematous congestions to which Caussade refers occur in the course of kidney and heart disease, but the tuberculin tests are negative and no tuberculous lesions are discovered at autopsy, although during life auscultation findings suggested an advanced tuberculous lesion. Their true nature is revealed by their changing position at times and their complete subsidence sooner or later in some cases, although in others they may persist indefinitely unless special measures are directed against the congestion. Two typical cases are cited of these apical congestions in the course of chronic nephritis and two with chronic mitral or aortic incompetency. Recurring hemorrhage from the lungs in these latter cases corroborated the diagnosis of tuberculosis, but the subsidence of the apical signs demonstrated that the hemorrhagic tendency was due to the heart trouble and not to tuberculosis. In another case of mitral insufficiency and nephritis the auscultation findings and repeated hemoptysis suggested tuberculosis, but the lungs cleared up under treatment of the heart and kidney disease and the findings became normal, confirming the negative findings of the tuberculin tests. In a youth of 16 with chronic adhesive pericarditis the auscultation findings seemed to reveal the presence of a cavity in one lung, but autopsy showed merely intense congestion of the right apex with not a trace of tuberculosis. When the edematous congestion surrounds a true tuberculous lesion, differentiation is delicate but very important, as the tuberculous lesion may be minute, while the perituberculous is very extensive. Two examples are given of cases of this kind, the prognosis being favorable if the perituberculous congestion is found to be variable or fleeting. In one of this group the edematous congestion developed after influenza and severe tuberculosis was diagnosed, but the signs all vanished in time under revulsive measures, and two years later the young man passed a rigid physical examination for a government position. The signs and auscultation findings in each of the above eight cases are given in detail.

49. **Carbon Dioxid Responsible for Hemolysis in Paroxysmal Hemoglobinuria.**—Bergh announces that study of the blood of three patients with paroxysmal hemoglobinuria has shown that carbon dioxid has much to do with the hemolysis. A thin layer of the defibrinated blood of these patients in a shallow dish placed for two hours in a glass bell filled with carbon dioxid showed pronounced hemolysis when the temperature was reduced a few degrees below ordinary body temperature. There was no hemolysis when the body temperature was maintained, and no hemolysis in numerous other tests with blood from healthy persons at any temperature. This research was suggested by Hamburger's statement that the resistance of normal red corpuscles to dilute salt solution is materially reduced under the influence of carbon dioxid.

51. **Etiology of Enlargement of the Prostate.**—Rothschild gives a number of illustrations to sustain his assertions that the enlargement of the prostate is the result of a chronic inflammation, the inflammatory foci lying around the mouths of the excretory ducts and thus causing stenosis or occlusion of these ducts with retention of the catarrhal secretion, dilatation and cystic degeneration, the process and results similar to those of retention in any glandular organ. The chronic prostatitis in question is a very long drawn out process, extending over years and decades, and it may be not only clinically latent, but the naked eye may be unable to detect histologic changes in the gland. The microscope, however, will reveal the signs of submucous chronic inflammation in the posterior urethra and of catarrhal proliferation and desquamation of the epithelium in the follicular pouches and outlets of the prostate. Some prostates contain less glandular substance than others, and the effect of the inflammation is felt less on this account. The findings reported confirm the lack of any rational basis for treatment of enlargement of the prostate by castration or severing of the vas deferens or ligation of afferent arteries—all of which are now abandoned. But the anatomic findings suggest the importance of systematic treatment of chronic prostatitis in prophylaxis of hypertrophy of the organ. This is the task of the general practitioner, and he should not fail to institute a three or four weeks' course of massage two or three times a year for several years after subsidence of the acute phase of prostatitis. This will counteract the stagnation of the secretions and development of deposits of round cells at different points, while it will promote the circulation through the blood vessels and lymphatics and favor absorption of inflammatory infiltrates. Of course, after fibrous connective tissue processes have developed, massage is no longer effectual. It may be usefully supplemented by other measures to promote absorption, such as brine and mud baths, etc.

52. **Sympathetic Epididymitis.**—Waelsch reports a case of frequently recurring pains in the scrotum evidently from acute congestion in a chronically inflamed organ, the result of reflex disturbances in the circulation, sometimes from emotional influences. Tough infiltration in the epididymis and vas can be palpated, but tuberculosis, gonorrhea and syphilis can be excluded in this case; a tendency to internal inguinal hernia on each side can not be regarded as responsible for the recur-

ring pains. The patient was a man of 31 and no benefit had been derived from the most varied treatment during the five years since the first pains were observed; the attacks of pain had grown constantly more severe and the intervals shorter, except that some attenuation had been observed quite recently under the bromids. Waelsch also reports a case of what he calls erotic epididymitis, a form of the sympathetic affection in which the painful congestion is the result of erotic excitement. The congestion subsided under rest and moist heat, but an infiltration still persists.

53. **Obstetrics in the Clinic and the Home.**—Puppel pleads for better instruction of the general practitioner in the indications for obstetric operations and for expectant management of childbirth in the dubious cases. He is convinced that greater familiarity with the use of the inflatable bag will render operative measures unnecessary in many more cases.

55. **Medicolegal Certificates.**—Among the various points of Marx's advice is the warning that each certificate should be made complete, that is, the questions of the judge or other authority should be given along with the answers, and the latter should be couched in language to correspond, so that any third lay party reading the certificate at any time would be able to understand the whole matter and judge it for himself. Another important point is for the physician to weigh the morbid state in comparison with the normal capacity of the individual. The third factor of importance in making out the certificate is the medical judgment of the single event, the accident, etc., assumed to be responsible for the condition. Marx warns further against positive assertions, urging the use of "probably," "possibly" or "nothing conflicts with the assumption that," to modify the positive statements. It is especially necessary to avoid such assertions as "X is mentally sound" as the verdict after a single office examination Such a positive assertion is permissible only after a long course of observation; the physician should state only that he had not been able to detect any signs of mental unsoundness during his examination.

63 *Spectroscopic Test for Occult Blood in Stool. (Neue spektroskopische hämochromogene Blutprobe der Faeces.) C. Karoly
64 Improved Joint for Artificial Knee. (Kniegelenk für künstliche Beine.) O. Vulpius.

56. **Opsonins and Pulmonary Tuberculosis.**—Wolff and Reiter are in charge of the policlinic for lung affections at Berlin, and they state that the opsonic index ranks just below the subcutaneous injection of tuberculin as the most delicate and reliable aid for diagnosis of tuberculosis. The opsonic index in health ranges from 0.85 to 1.15; a permanently low index suggests a chronic, possible stationary, tuberculous process, while a very low fluctuating index indicates progressive infection. They regard the ocular reaction as the most unreliable of the tubercle reactions; the statement that it indicates only active tuberculosis has not been confirmed by their experience.

58 **Organ Treatment of Cataract.**—Schirmer's experiments failed to confirm Römer's hypothesis in regard to the absorption of lens substance and its therapeutic reaction. He cites Königshöfer's negative experiences over ten years ago with such organotherapy. Börnstein has observed fatal anaphylaxis in rabbits fed with an alien albumin, which suggests the necessity for caution with these organ extracts.

59. **The Alleged Specific Reaction in the Blood of the Insane.**—Hübner and Selter have applied the cobra toxin hemolytic test in 82 cases, but their findings differ materially from those reported by Much. They were positive in less than 50 per cent. of the cases of dementia præcox and manic depressive insanity, while they proved positive also in a number of psychoses, neuroses and in organic brain and spinal cord affections.

62. **Improved Quantitative Test for Sugar in Urine.**—Citron regards the technic described as marked progress; even the novice is able to read off the percentage of sugar in the urine in a few minutes with automatic accuracy, and only a single dish is required for the test, a single heating, and no filtering. It is a modification of the iodometric modification of Fehling's quantitative test. The iodometric method consists in heating the urine with Fehling's solution, filtering, treating with sulphuric acid and potassium iodid, and titrating the iodin with sodium thiosulphate and starch. It is based on the principle that the sugar precipitates a proportionate amount of the copper in the Fehling solution and that the precipitated cuprous oxid remains behind on the filter. By the action of the sulphuric acid and potassium iodid on the filtrate, one atom of iodin is liberated for each molecule of the copper sulphate. The tedious decolorization of the Fehling test is avoided, and the iodin reaction in its place is much plainer. Only the copper still in solution—not that already reduced—induces the liberation of the iodin, and the cuprous oxid becomes quantitatively transformed into cuprous iodid. Ten c.c. of the potassium-sodium tartrate solution are placed in a porcelain dish and 10 c.c. of the copper solution are measured out and nearly all is added, the mixture thoroughly stirred. Then exactly 1 c.c. of urine is added, and when all is dissolved, the mixture is heated over a small flame for a minute and a half, to boiling, and then cooled by placing the dish in a vessel of cold water. (While it is cooling the starch solution is prepared.) Then 4 c.c. of a 25 per cent. solution of sulphuric acid are added, when a thick, viscid precipitate is at once thrown down. The solution of sodium thiosulphate is then added from a burette graduated for percentages, a line at a time, and a few c.c. of the starch solution are added. The fluid then turns deep blue or possibly a little more of the sulphuric acid solution and starch solution may be required. More of the thiosulphate solution is then added, a line at a time, until the fluid turns milk white and remains so even when it is stirred. The rest of the copper solution is then added and the rinsing water. If the fluid still remains white the percentage line on the burette is the index of the proportion of sugar in the urine. If a blue tint returns, more of the sodium thiosulphate is added, drop by drop, until a permanent milky tint results. Citron uses a special iodometric burette graduated for urine percentages and a special pipette graduated for 1 c.c. of urine, used with a syringe with a capacity of 2 c.c. The solutions used are: *a*, 34.639 gm. of copper sulphate dissolved in 500 gm. distilled water, to which 1 c.c. of sulphuric acid is added to prevent formation of copper carbonate; *b*, 173 gm. potassium-sodium tartrate, 50 gm. sodium hydroxid and 100 gm. potassium iodid dissolved in 500 c.c. water; *c*, a one-fifth normal solution of sodium thiosulphate containing also 0.1 per cent. sodium arsenate to make it keep better; *d*, a 25 per cent. solution of sulphuric acid, and *e*, the starch solution which he makes by dissolving in half a reagent glass of water a small piece, the size of a hazel nut, of a paste preparation used by photographers. The starch solution is heated to boiling and then cooled.

63. **New Spectroscopic Test for Occult Blood in the Feces.**—Karoly uses pyridin and ammonium sulphid for the test; the reduction is so complete that the test is ten times as sensitive as other spectroscopic methods. The feces are washed with ether and filtered; the residue is extracted with concentrated acetic acid and 0.5 c.c. are mixed with 1 c.c. pyridin; then from 1 to 3 drops of the ammonium sulphid are added. The fluid is limpid and gives the spectrum for hemochromogen. The test is a little less sensitive than the guaiac and aloin test, but more so than the benzidin test. These other tests can be applied for control, if desired, with some of the acetic acid extract.

66 *Fever and Its Treatment. (Fieber und Fieberbehandlung.) L. Lichtwitz. Commenced in No. 17.

66. **Treatment of Fever.**—Lichtwitz reviews the history of the management of fever as it has varied with the prevailing conceptions of the nature of the high temperature in disease, and outlines the present accepted treatment. This is based on the conception that fever is a salutary reaction on the part of the organism, but that, like all such processes in nature, the reaction may be excessive and overshoot the mark. It is the physician's task, therefore, to watch over the fever, doing nothing if all is going well, but ready at any moment to intervene to keep the salutary reaction within due bounds. If the patient's consciousness is disturbed, the breathing becoming more superficial, the assimilation of nourishment suffering, then gentle antipyretic measures are in order. For this the specific drugs should be given the preference, quinin in malaria, salicylic acid in acute rheumatism, and in other fevers mild external applications of water, with more energetic measures in case of excessively high fever, with digitalis, camphor and caffein in case of collapse.

68 *Congenital Tuberculosis. H. Rietschel.
69 Wet Nurses in Ancient Alexandria. (Die Amme im alten Alexandrien.) W. Schubert.

67. **Lactic Acid and General Metabolism in Infants.**—Klotz has found that small amounts of lactic acid, not more than 1 or 1.5 gm., seem to reduce saponification and promote the metabolism in general when administered to infants. The metabolic findings in six are tabulated in detail; some of the infants were healthy and others recovering from some acute gastrointestinal disturbance. Larger doses render the metabolism more sluggish.

68. **Congenital Tuberculosis.**—Rietschel relates the particulars of a case in which the physician delivered the child of a woman of 30 in advanced tuberculosis, wrapped it in a towel and placed it on a bed ten feet from the mother. In twenty minutes it was bathed in an adjoining room by the nurse who had arrived too late for the birth. The child was then taken at once to a foundlings' home, where it was received before it was forty-five minutes old. There were no signs of tuberculous infection at first, but they developed after a month or so, and the child died of generalized tuberculosis at the fourth month. Sitzenfrey has reported two similar cases in which infection from the mother after birth seems positively excluded, and yet generalized tuberculosis developed in from three to six months. Rietschel is inclined to attribute the infection to contamination during the stress of delivery, intrapartum infection. As young infants are unable to develop antibodies, such infection during birth is almost inevitably fatal, whether the child remains with its mother or not. When the tuberculosis does not develop until after the sixth month, the infection was probably acquired after birth. He is convinced that the intrapartum infection is much more common than generally recognized, and that there are no grounds for assuming a latency of the tubercle bacilli in the infant organism, which is one of the premises of Behring's theory of tuberculous infection in early infancy.

Münchener medizinische Wochenschrift

July 6, LVI, No. 27, pp. 1361-1408

70 *Clinical Importance of [illegible] psin in the Blood. (Bedeutung d[illegible] im Blute.) L. Jacob. Id. in Gyn[illegible]
71 *Special Reaction in Blood in Umbilical Cord. (Besondere Reaktion im [illegible] orener.) F. Bauer.
72 *Etiology of [illegible] I. Schneider.
73 *Trigeminal [illegible] P. Preiswerk.
74 *Diagnosis of [illegible] Blood. (Zur Diagnose der Bleivergiftung aus dem Blute.) A. Trautmann.
75 Simple Office [illegible] Salt and Urea Content of Urine. [illegible] Sprechzimmer den Salz- und den [illegible] feststellen?) Wunder.
76 Treatment [illegible] ativen Behandlung der Knochenb[illegible] [illegible]

70. **Antitrypsin Index in the Blood.**—Jacob has been applying the antitrypsin test in 100 cases of various affections at Moritz's clinic at Strasburg. The findings show that the proportion of antitryptic ferment in the blood is much increased in a number of different morbid conditions. Constant in cachexia, it is found also in all conditions accompanied by changes in the white corpuscles and also in some cases without these findings. The reaction occurs in too many conditions to be regarded as of any importance for differentiation. Becker reports from Veit's clinic the findings in 135 gynecologic cases. The reaction was positive with carcinoma and also with anemia, chronic septic processes and also after delivery. The research at both clinics was with the Fuld technic.

71. **Serum Reaction in the Insane and in the New-Born.**—Bauer has found the same reaction which Much found in the insane and called the "psychoreaction," in the blood in the umbilical cord of 14 out of 17 infants examined, while there was no trace of the reaction with the serum of 25 older children.

72. **Etiology of Ophthalmic Hemicrania.**—Schneider has encountered a typical case in which the attacks followed some exposure to cold or to infection. If the findings in this case are confirmed by others, the symptoms can be ascribed to the action of toxins—not a specific infection, but a specific reaction on the part of predisposed individuals to "catching cold," etc.

73. **Trigeminal Neuralgia of Dental Origin.**—Preiswerk reports two cases in men in which non-erupted teeth caused a syndrome simulating severe trigeminal neuralgia.

74. **Diagnosis of Lead Poisoning from the Blood.**—Trautmann has been comparing the blood picture in 233 workers with lead, 100 anemic patients and 100 healthy individuals. The basophile granular red corpuscles were found in much larger proportions in the workers on lead, while in the anemic and the healthy they were below 100 per million. When over 100 per million are found in persons exposed to lead poisoning the latter is almost certain. In forensic cases he suggests 300 per million as the limit. Examination of the blood is thus able to reveal lead poisoning in its incipiency.

82 Campaign against Malaria in Europe. L. Sofer.
83 *Chloral as Deodorizer in Gangrene of the Lungs. A. Siegmund. Id. Langgaard.

77. **Ferric Chlorid-Gelatin Treatment of Gastric Ulcer.**—Bourget states that he has been constantly successful with his ferric chlorid method of treating round gastric ulcer, the ulcer promptly healing in fourteen days or less, and he has never witnessed any mishaps from it in nine years of experience. The objection has been made to the method that it requires the use of a stomach tube which some shrink from using with gastric ulcer, but he has never had any trouble from this cause, although he has used the stomach tube thousands of times. Nevertheless, he has modified his technic so as to dispense with the use of the stomach tube for introducing the 1 per cent. solution of ferric chlorid. This is accomplished by mixing the chlorid with a gelatin. He dissolves with gentle heat 100 parts gelatin in 100 parts water and 100 parts glycerin, and when fully dissolved adds 50 parts of liquid ferric chlorid. The mixture is warmed and stirred to a homogeneous mass and cooled in the form of dice, each containing 1 c.c. He allows the ulcer patient at 8 a. m. some milk and zwieback; at 10 a. m. one of the chlorid tablets is taken and in half an hour from 100 to 150 gm. of an alkaline drink. This is made by dissolving in 1 liter of cold water one of ten powders made from 8 gm. sodium bicarbonate, 4 gm. sodium phosphate and 2 gm. sodium sulphate. The noon meal is rice cooked in milk, followed at 3 p. m. with another chlorid gelatin tablet, followed half an hour later with 150 gm. of the alkaline drink. At 6 p. m. rice, at 9 another chlorid tablet and at 10 p. m. 150 gm. of the alkaline

water. The pains rapidly subside and healing is soon complete, he says, under this treatment. In the severe cases with much hemorrhage he rinses out the stomach at once with the 1 per cent. ferric chlorid solution and then follows with the gelatin. In every instance the hemorrhagic tendency was promptly arrested, and he has never had a recurrence of bleeding. Test tube experiments have shown that the ferric chlorid-gelatin tablets are digested by the gastric juice. The chlorid cauterizes the ulcer and the iron helps to restore the hemoglobin lost in the hemorrhage.

78. **Chronic Diarrhea in Children.**—Schütz refers to the diarrhea in children, induced by imperfectly digested food, "dyspeptic diarrhea;" the undigested food passes into the intestines in such form that it sets up irritation. The diarrhea is the admirable defensive reaction on the part of the bowel, and no attempt should be made to check it with drugs, as they do not remove the cause. Treatment should be directed against the causal digestive disturbances and the diet regulated to exclude such articles as examination of the stool shows to be the ones which the stomach or intestines are unable to cope with and normally digest. The food should be such as leaves no waste, and any food which escapes normal digestion becomes useless waste and ballast which tax the bowel and irritate it. The aim should be to establish the balance between the functional capacity of the gastrointestinal tract and the diet, such a balance as adults find on an ordinary mixed diet. His experience with fifteen children presenting typical examples of this dyspeptic diarrhea has demonstrated the importance of regulation of the diet based on examination of the stool so as to exclude from the diet such articles as are seen to escape the action of the digestive processes. Starch insufficiency usually righted itself first in his cases, and he never found it necessary to exclude all carbohydrates. A strictly fluid diet may be necessary in the severer cases, and this is one of the most potent means of conquering diarrhea, he emphasizes, no matter what the underlying disturbance. One child of 5 with severe starch and fat dyspepsia and diarrhea for years gained about 10 pounds in six weeks when the diet was regulated along these lines. Some of the children had severe relapses whenever they attempted to return to ordinary diet. They had to do without vegetables and butter for two years, and even at the end of four years an attempt to eat coarse bread, raw fruit and unsieved vegetables caused the return of the dyspeptic diarrhea. Not until after the fifth year could they eat ordinary mixed diet, but they thrived on the restricted diet and weighed even more than the average for their years. Lavage of stomach and bowel is a valuable adjuvant in many cases.

81. **Rubber Gloves in General Obstetrics.**—Mende has devised a method of keeping rubber gloves sterile and unimpaired in their elasticity and impermeability and always ready for use, and urges their advantages. If for no other reason, gloves are useful on account of the peace of mind of the obstetrician, as they spare the general practitioner all worry for fear the disinfection of his hands has not been complete. The gloves are first scrubbed with warm water, inside and out, and then rinsed and examined for any defect. They are then transferred to a pot of boiling water with tight cover and allowed to boil for five minutes—no longer—and then held up by the fingers with forceps until thoroughly drained, then placed in a preserve jar filled two-thirds full of glycerin which has been previously heated to boiling point and had a little mercuric chlorid added in the proportion of 1 or 2 per thousand. The jar is thoroughly scrubbed and sterilized beforehand and the cover and rubber ring are fitted on air-tight. The gloves are drawn on the hand under water. The fluid enters the glove and opens out the fingers, making it very easy to draw on the glove. The main point in the management of the gloves is not to boil them for more than five minutes and not to leave them in any fluid except the glycerin a moment longer than is necessary. The jars stand wear well; Mende has never had one break even when his carriage or sleigh was overturned.

83. **Chloral as a Deodorizer.**—Siegmund calls attention to the prompt deodorizing properties of chloral, especially for a mouth wash and for the sputum cups in cases of gangrene of the lungs. Specimens kept in a weak solution of chloral have been used for years for demonstrations without odor. Langgaard has a specimen of fish which has kept perfectly for forty years in a glass jar filled with a solution of chloral.

93 *Serum Reaction in the Insane. (Verhalten verschiedener menschlicher Sera und Blutkörperchen bei der Hämolyse durch Kobragift.) J. A. Hirschl and O. Pötzl.
94 *Diagnosis by Elimination of Drugs in Sputum. (Sputumdiagnose.) F. Falk and F. Tedesko.
95 *Operative Treatment of Trigeminal Neuralgia. E. Hulles.
96 *Operative Treatment of Carcinoma of the Larynx. H. Koschier.

93. **Serum Reaction in the Insane and Others.**—Hirschl and Pötzl report a number of tests of the hemolytic reaction to which Much has recently called attention as specific for the serum in certain forms of insanity. Their experience with fifty cases has confirmed the peculiar high resistance to hemolysis by cobra venom in cases of dementia præcox of the catatonic and hebephrenic forms.

94. **Diagnosis by Means of the Sputum.**—Falk and Tedesko report the conclusions of research which show that salicylic acid is eliminated in the sputum in pneumonia, while there is no such elimination in bronchitic affections. Patients taking 2 gm. (30 grs.) of sodium salicylate gave positive or negative findings according as the morbid process was in the lungs or bronchi. Positive findings were also obtained in pulmonary tuberculosis, more pronounced in the acute cases, but in none so extensive as in pneumonia and pneumonic gangrene. No other drugs seem to pass into the sputum in this way, and they suggest that this property of being eliminated in the sputum renders sodium salicylate peculiarly appropriate in treatment of pneumonic processes, as it insures local action at the points of least resistance. The other drugs tested were methylene blue, antipyrin, guaiacol, etc. They describe the colorimetric technic followed in testing for the salicylic acid.

95. **Operative Treatment of Trigeminal Neuralgia.**—Hulles reviews von Eiselsberg's surgical experience with 63 cases of trigeminal neuralgia during the last ten years with the ultimate outcome. His conclusions are that drugs may relieve and banish the pain temporarily, but are unable to produce a permanent cure. Peripheral operations are almost certain to be followed by recurrence, the interval about the same as with medicinal treatment. Recurrence is also frequent after resection at the base of the skull; excision of the Gasserian ganglion is the only certain cure. If the case is very severe and all three branches are involved, the latter operation should be done without wasting time on the others. If not so severe, injections of alcohol, repeated at need, may prove sufficient or resection at the base of the skull in case only two branches are involved.

96. **Treatment of Carcinoma of the Larynx.**—Koschier tabulates the details of 28 cases of cancer of the larynx in which he operated during the last ten years and reviews series published by others. In 18 cases with an interval of over three years since the operation, 8 of the patients are free from recurrence to date, including 4 out of 5 treated by laryngofissure; 2 out of 10 treated by partial laryngectomy, and 2 out of 3 treated by the total operation. Scarcely more than a fourth of all the cases observed were operable, although

incipient cancer in the larynx induces hoarseness for months, but the patients seldom consult a physician for this alone. On the other hand, some physicians overlooked the malignant disease and merely prescribed a gargle or treated the patient with a course of sprays for months.

106 Combined Version and Metreurysis. (Kombinierte Wendung und Metreuryse.) A. Rieck.

101. Decapsulation of the Kidney in Eclampsia.—Alsberg reports four cases in which favorable results were obtained by decapsulation of both kidneys in threatening eclampsia. In two cases the convulsions ceased at once and in the others they become very much milder, although persisting for a short time. One patient was a primipara of 18 with seven convulsions between delivery and decapsulation, but none afterward. The diuresis increased materially in all the cases after the operation, although in only one case did the kidney seem to be in the "glaucoma condition." He regards the operation as indicated when the convulsions are frequent and growing worse, the coma profound, the pulse failing and anuria impending.

103. Momburg Belt in Postpartum Hemorrhage.—Rieländer reports the application of the constricting belt technic in nine cases of postpartum hemorrhage from atony, placenta prævia or laceration of the cervix. No effect was apparent on the hemorrhage, while the general condition suffered to a greater or less degree, the pulse failing, and in one case diarrhea and retention of urine followed the application of the belt. The reason for this failure of the belting technic to arrest postpartum hemorrhage is possibly to be found in the fact that the stomach and intestines are not empty as when a patient is prepared for an operation. Another factor may be the high location of the fundus of the uterus, which renders it impossible to apply the rubber tube around the waist, so that it has to be pushed up close to the costal arch.

104. Operative Treatment of Acute Peritonitis During Confinement.—In Kritzler's case the peritonitis was evidently the result of rupture of an old encapsulated appendiceal abscess. The patient was apparently moribund from the peritonitis, but recovered promptly after laparotomy with provision for drainage and thorough rinsing out of the abdominal cavity, with an artificial anus, injection of atropin to stimulate peristalsis and stimulants. The case encourages intervention even in the most apparently hopeless cases. The procedure relieves the tension of the abdominal wall and may transform the prognosis.

108 *Efficacy of Quinin in Whooping Cough. (Chinino nella pertosse.) L. Andalo.

108. Quinin in Whooping Cough.—Andalo has been giving quinin in an epidemic of whooping cough, and states that the disease seemed to be aborted in every case in which quinin was given in large doses systematically for several days in succession and the drug retained. The pertussis was of an unusually serious type, both on account of its intensity, the number of complications observed and of adults affected. His experience suggests an actual causal efficiency of the drug. He has always found exceptional tolerance for quinin in children, no appreciable disturbances having been noted in a number of children in an endemic focus of malaria who took by mistake, for malaria, 6 and 7 gm. of quinin bisulphate. For pertussis he did not hesitate to inject in the course of a day 0.5 gm. of acid quinin hydrochlorid for infants and 1 gm. for children up to the age of 5. On cessation of the tendency to vomit he gives the drug by the mouth and keeps it up for eight or ten days, by which time the disease has usually completely subsided. He relates a number of instances to show the prompt relief from the quinin. One patient had pertussis during confinement, but all symptoms vanished the sixth day under 1.5 gm. of the quinin daily.

113 *Sarcoma of the Rectum. (Zur Kasuistik des Rektalsarkoms.) E. Key.

112. Operative Treatment of Gastric and Duodenal Ulcers.—Dahlgren's monograph of 172 pages discusses a number of points of interest from his own and others' experience, with summaries of 88 case histories. Among the points emphasized is the necessity for excision of a "callous" ulcer and duodenal ulcer as the only means of cure and prevention of cancerous degeneration. He is convinced that gastroptosis is in certain cases the primary pathologic factor and that it is amenable to gastropexy. A laparotomy may be indicated even for uncomplicated gastroptosis without ulcer, much dilatation or cicatricial stenosis if symptoms indicate a kinking of the bowel and internal or bandage treatment has failed to relieve. Gastropexy is preferable to gastrojejunostomy in such cases, as it avoids the liability to the vicious circle and peptic ulcer. He does not approve of jejunostomy for ulcer except for perforated ulcer with stenosis and extreme debility, rendering a gastrojejunostomy too risky. Gastrostomy is preferable, but he would restrict it to the second place. In case of postoperative paralysis of the bowel, he empties the intestine by an incision, milking out the contents until it is so empty that it subsides spontaneously into the abdomen as the lips of the wound are held apart. To prevent adhesions he pours a large quantity of sterile oil into the abdominal cavity afterward, having found this very effectual. The abdominal incision must be made large enough to enable the mesentery to be drawn out with the intestine without incarceration, and the intestines must be kept constantly moist and warm with hot compresses and salt solution repeatedly poured over them.

113. Rectal Sarcoma.—Key has encountered four cases and cites one from Ekehorn's practice; the patients mostly succumb to recurrence in a few months after operation.

95. **Operative Treatment of Trigeminal Neuralgia.**—Hulles reviews von Eiselsberg's surgical experience with 63 cases of trigeminal neuralgia during the last ten years with the ultimate outcome. His conclusions are that drugs may relieve and banish the pain temporarily, but are unable to produce a permanent cure. Peripheral operations are almost certain to be followed by recurrence, the interval about the same as with medicinal treatment. Recurrence is also frequent after resection at the base of the skull; excision of the Gasserian ganglion is the only certain cure. If the case is very severe and all three branches are involved, the latter operation should be done without wasting time on the others. If not so severe, injections of alcohol, repeated at need, may prove sufficient or resection at the base of the skull in case only two branches are involved.

96. **Treatment of Carcinoma of the Larynx.**—Koschier tabulates the details of 28 cases of cancer of the larynx in which he operated during the last ten years and reviews series published by others. In 18 cases with an interval of over three years since the operation, 8 of the patients are free from recurrence to date, including 4 out of 5 treated by laryngofissure; 2 out of 10 treated by partial laryngectomy, and 2 out of 3 treated by the total operation. Scarcely more than a fourth of all the cases observed were operable, although

incipient cancer in the larynx induces hoarseness for months, but the patients seldom consult a physician for this alone. On the other hand, some physicians overlooked the malignant disease and merely prescribed a gargle or treated the patient with a course of sprays for months.

106 Combined Version and Metreurysis. (Kombinierte Wendung und Metreuryse.) A. Rieck.

101. Decapsulation of the Kidney in Eclampsia.—Alsberg reports four cases in which favorable results were obtained by decapsulation of both kidneys in threatening eclampsia. In two cases the convulsions ceased at once and in the others they become very much milder, although persisting for a short time. One patient was a primipara of 18 with seven convulsions between delivery and decapsulation, but none afterward. The diuresis increased materially in all the cases after the operation, although in only one case did the kidney seem to be in the "glaucoma condition." He regards the operation as indicated when the convulsions are frequent and growing worse, the coma profound, the pulse failing and anuria impending.

103. Momburg Belt in Postpartum Hemorrhage.—Rieländer reports the application of the constricting belt technic in nine cases of postpartum hemorrhage from atony, placenta prævia or laceration of the cervix. No effect was apparent on the hemorrhage, while the general condition suffered to a greater or less degree, the pulse failing, and in one case diarrhea and retention of urine followed the application of the belt. The reason for this failure of the belting technic to arrest postpartum hemorrhage is possibly to be found in the fact that the stomach and intestines are not empty as when a patient is prepared for an operation. Another factor may be the high location of the fundus of the uterus, which renders it impossible to apply the rubber tube around the waist, so that it has to be pushed up close to the costal arch.

104. Operative Treatment of Acute Peritonitis During Confinement.—In Kritzler's case the peritonitis was evidently the result of rupture of an old encapsulated appendiceal abscess. The patient was apparently moribund from the peritonitis, but recovered promptly after laparotomy with provision for drainage and thorough rinsing out of the abdominal cavity, with an artificial anus, injection of atropin to stimulate peristalsis and stimulants. The case encourages intervention even in the most apparently hopeless cases. The procedure relieves the tension of the abdominal wall and may transform the prognosis.

108 *Efficacy of Quinin in Whooping Cough. (Chinino nella pertosse.) L. Andalo.

108. Quinin in Whooping Cough.—Andalo has been giving quinin in an epidemic of whooping cough, and states that the disease seemed to be aborted in every case in which quinin was given in large doses systematically for several days in succession and the drug retained. The pertussis was of an unusually serious type, both on account of its intensity, the number of complications observed and of adults affected. His experience suggests an actual causal efficiency of the drug. He has always found exceptional tolerance for quinin in children, no appreciable disturbances having been noted in a number of children in an endemic focus of malaria who took by mistake, for malaria, 6 and 7 gm. of quinin bisulphate. For pertussis he did not hesitate to inject in the course of a day 0.5 gm. of acid quinin hydrochlorid for infants and 1 gm. for children up to the age of 5. On cessation of the tendency to vomit he gives the drug by the mouth and keeps it up for eight or ten days, by which time the disease has usually completely subsided. He relates a number of instances to show the prompt relief from the quinin. One patient had pertussis during confinement, but all symptoms vanished the sixth day under 1.5 gm. of the quinin daily.

113 *Sarcoma of the Rectum. (Zur Kasuistik des Rektalsarkoms.) E. Key.

112. Operative Treatment of Gastric and Duodenal Ulcers.—Dahlgren's monograph of 172 pages discusses a number of points of interest from his own and others' experience, with summaries of 88 case histories. Among the points emphasized is the necessity for excision of a "callous" ulcer and duodenal ulcer as the only means of cure and prevention of cancerous degeneration. He is convinced that gastroptosis is in certain cases the primary pathologic factor and that it is amenable to gastropexy. A laparotomy may be indicated even for uncomplicated gastroptosis without ulcer, much dilatation or cicatricial stenosis if symptoms indicate a kinking of the bowel and internal or bandage treatment has failed to relieve. Gastropexy is preferable to gastrojejunostomy in such cases, as it avoids the liability to the vicious circle and peptic ulcer. He does not approve of jejunostomy for ulcer except for perforated ulcer with stenosis and extreme debility, rendering a gastrojejunostomy too risky. Gastrostomy is preferable, but he would restrict it to the second place. In case of postoperative paralysis of the bowel, he empties the intestine by an incision, milking out the contents until it is so empty that it subsides spontaneously into the abdomen as the lips of the wound are held apart. To prevent adhesions he pours a large quantity of sterile oil into the abdominal cavity afterward, having found this very effectual. The abdominal incision must be made large enough to enable the mesentery to be drawn out with the intestine without incarceration, and the intestines must be kept constantly moist and warm with hot compresses and salt solution repeatedly poured over them.

113. Rectal Sarcoma.—Key has encountered four cases and cites one from Ekehorn's practice; the patients mostly succumb to recurrence in a few months after operation.

119 **Early Differentiation of Pulmonary Tuberculosis. (Bidrag* til Lungetuberkulosens tidlige Klinik.) C. A. Blume. Commenced in No. 23.

117. Operations on the Kidneys.—Kaarsberg reports two cases of trauma of the kidneys in one of which the lower part of the kidney was torn as if cut off with a dull knife and yet there was no trace of injury of the skin. The man had fallen under a horse. In another case nephrotomy was done on the kidney left after nephrectomy; complete recovery followed removal of a few calculi. In a fourth case the patient succumbed to heart failure after nephrectomy in puerperal pyonephrosis. This last experience has confirmed him in the view that surgical treatment should be undertaken earlier in such cases.

119. Early Differentiation of Tuberculosis.—Blume analyzes his experiences with 110 cases of pulmonary tuberculosis in adults in which the diagnosis was made by discovery of tubercle bacilli in the laryngeal secretion. The patients had little or no cough and irregular or no expectoration, and differentiation was possible only by examination of the laryngeal mucus. Only 1 bacillus was found in 8 cases, from 2 to 5 in 65, from 6 to 10 in 12, and from 50 to 100 in 3. The larynx was generally congested, but there were *no* subjective disturbances in the majority, merely a little hoarseness in a few. In 12 men and 12 women there were signs of anemia, and the general weakness first suggested tuberculosis; in 10 other men and 3 women pains in the chest were the first symptom, and at least 4 had been under treatment on this account for supposed rheumatism or gout. He discusses the anatomic origin of the pain, and cites some typical examples of each group. In a third group of 15 men and 20 women nervous and psychic symptoms predominated in the clinical picture of the incipient tuberculosis. The physical findings were negative or dubious, and the nervous symptoms were evidently of toxic origin; a course of tuberculin treatment cured these symptoms completely in some of the cases. The tuberculous process *may generate toxins* both during a progressive and a retrogressive course, as he shows by several examples. He agrees with the view that exophthalmic goiter may in certain cases be due to the tuberculous toxin, reporting a case in a man of 20 supposed to be suffering from gastric catarrh and exophthalmic goiter. Tubercle bacilli were discovered in the laryngeal secretion taken directly from the larynx, and treatment directed against the tuberculous infection had a favorable effect on both the stomach and the other affection. In a fourth group symptoms on the part of the stomach predominated in 9 men and 22 women, vomiting or paroxysmal pain, evidently the work of the tuberculous toxin causing arrosions, inflammation or hypersecretion. The experiences related with patients in this group throw light on many puzzling cases of stomach affections; gastrosuccorrhea under these circumstances may be a defensive reaction on the part of the stomach to the tuberculous toxin. He has witnessed marked benefit on the stomach symptoms in many cases from antituberculosis treatment. *He also calls attention to the combination* of the tuberculous toxin and the toxin from some other infection as liable to induce a stormy reaction on the part of the stomach. In one such case the patient, a man of 24, was taking the usual course of tuberculin treatment when suddenly symptoms developed suggesting perforation of the stomach, but subsiding as operative intervention was being considered, and explained by the onset of symptoms of follicular tonsillitis. The unsuspected incubation phase of the tonsillitis caused another infectious toxin to be superposed on the tuberculous toxin, the resulting syndrome deceptively simulating perforation of the stomach, although the pre-existing tuberculosis was known in this case. This intensive form of reaction may simulate croup, spasm of the pylorus, appendicitis and kidney colic, or the heart may feel the effect most prominently, with resulting transient tachycardia, or there may be vertigo or entire loss of consciousness. In one of his cases an annually recurring winter cough seemed to be vicariously substituted one year by kidney colics. Bladder colics were observed in one little girl.

Address

THE SCOPE OF PREVENTIVE MEDICINE

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON PREVENTIVE MEDICINE AND PUBLIC HEALTH OF THE AMERICAN MEDICAL ASSOCIATION, ATLANTIC CITY, 1909.

J. H. WHITE, M.D.
Surgeon United States Public Health and Marine-Hospital Service
NEW ORLEANS

There is—there can be—no higher specialty in medicine than that for which this Section stands, and we must present this to the public in such unmistakable terms that full recognition shall be accorded both to the sanitarian and to the profession as a whole, for neither can stand alone, as I hope presently to show. It is sheer waste of ability and time for the members of this Section to tell each other what they already know, and even the general distribution of *new matter* by the pioneers of the Section can not, in the nature of things, be so broadly useful as the same character of work would be, and is, in our truly great medical Section. Our greatest function, it seems to me, lies in the fact that we are the connecting link between that great medical body which handles the vast majority of the diseases we would prevent and the general public, the victim of those diseases.

This being an undisputed fact, we should have in mind constantly the two duties which follow this fact as naturally as the day follows the night. We must impress on the public the vast import to them of preventive medicine; we must show them that health means wealth and happiness, to the first very frequently and to the last always a necessary adjuvant.

In last year's Address on Medicine Dr. Thayer very properly said that but for sanitation there could be no Panama Canal; and is it not equally a fact that but for the incessant labor of men poorly paid, or paid not at all, every aggregation of people calling itself a city, even in the temperate zone, would be a focus of endemic disease, and cities of a million inhabitants unspeakable pest-holes, while such as New York, London, Paris, Berlin could not exist?

So much for the value to mankind of our work. These facts are reasons strong enough to justify us, and we shall continue to push forward, always seeking better results, whether recognized or not, content to serve our people as best we may, leaving our reward to their own sense of justice—and oh, the pity of it!—to be so often rewarded by abuse.

We should, for the better advancement of our work, make every possible effort to place the utilitarian aspect of that work before our law-makers and insist that they at least appropriate as much for the protection of their wives and little ones as for that of their swine, cattle and poultry. They might justly have claimed in the past that we had not shown ability to protect them, but this can not be said now.

It is something more than accident that last year Burrell and Thayer in the general orations and Drs. Edsall, Evans, Hurty and others advocated a campaign of education of our people. Such coincidence of thought means that we are ourselves awake and shall awaken our people to their duty to themselves and shall make it plain to them that no man has a right so to keep his house or so to live his life in a civilized community as to jeopardize his neighbor's health or happiness. It means that *we* shall teach all our people that the duty of keeping clean in a physical sense is as high as that of moral cleanliness and a prerequisite to a justified claim of "civis Americanus sum."

The practitioner of medicine saves lives one at a *time, and right noble is his calling.* You save lives by thousands. Is it not infinitely wiser to prevent the pollution by sewage of a stream supplying a city of a million than to fight that pollution in the bodies of 10,000 innocent victims of filth, or even to attempt the repurification of 100,000,000 gallons of that filth-laden water every day? Is it not better far to prevent the pollution of our food, houses, vehicles and streets by tuberculosis than to spend millions on treatment and then see our loved ones die by tens of thousands?

Is it not cheaper to spend a hundred millions of dollars and rid our country of every anopheles and stegomyia than to see business wither at flood-tide under the blighting grip of yellow fever, and our kindred and friends perish from the pest, while malaria takes its yearly tribute of thousands of lives in our country and destroys earning power to the extent of probably $50,000,000 annually and perhaps double *that?*

Shall we not vaccinate all our people at a cost of 25 cents each rather than leave some hundreds to die annually and some other hundreds of thousands to be branded with scars, a living shame to the community?

All these things we must bring forcibly and clearly before our people, and to do this we must cultivate our relations with the family physicians. They are closer to the people than we can ever be, and if we arouse their activities we will assure our ends. We must keep in close touch with them, and, indeed, we should enlist as many of them in this Section as possible, because without their help we can do nothing, and without the presence of some of their brightest and best, which, I am thankful to say, we have, at these meetings, we can not keep in as intimate association with them as we must. Fortunately, many of these able men are directly interested in sanitary science and are part and parcel of this Section, thus giving us the very opportunity we seek and should gratefully embrace to further arouse their interest to create an epidemic of sanitary enthusiasm on their part.

We must enlist the interest of our brethren, the pediatrists and the internists and get them to see and know the pitfalls in the path of the women and children under their care. We must lead them to take enough interest to play the part which a good old gentleman of the old school contemptuously called "dry nurse to the family."

We must start with the little ones, and, after seeing that their mothers are instructed in the hygiene of food and clothing, remove the notion that the children must of necessity have measles, whooping-cough, etc., and the sooner the better, by showing them that these diseases are ideal foundations on which to build future woe in the shape of tuberculosis.

We must teach parents that the sanest weapon with which to fight tuberculosis in their offspring is a good, sound body in which every atom of resisting power is developed by robust health to its maximum efficiency, that the development of the child's physical well-being is as sacred a duty as the development of its mind or morals, and is indeed the only proper foundation for intellectual vigor; that the boy whom they fain would bring up to be the grand man of the future must have sound lungs, stomach, eyes, teeth, etc., and good muscular development to enable him to meet his competitors on equal terms; that only in a healthy child can they realize all their hopes.

We must follow this teaching throughout, enlisting the aid of all branches of the profession, encouraging with all our might the tendency toward supervision of eyes and mouth of public school children, and every other similar movement; holding up the hands of men like Evans, who would not be content with mortality statistics in tuberculosis, but wants to find the morbidity as well, in order that medicine may work its rightful end and heal the sick. Finally, there is another and a high duty before us—the duty of doing what we can toward bettering health administration all over the country.

The time has passed, if it ever existed, when by virtue solely of the degree of M.D. a man is fitted to assume the duties and vast responsibilities of health officer. Although unfortunate, it is too true that even with special education we can not be sure of the innate ability to apply the knowledge held. We can, at least, be sure that we are not doing anything so utterly absurd as we have been doing under the old system of appointment, with merit only as an accidental qualification.

It is undeniable that some of these round pegs in square holes have adjusted themselves to these important positions and have proved brilliant successes, but these cases are exceptional and only go as parallels to the fact that a brilliant soldier like Napoleon can occasionally be a brilliant law-giver, not at all indicating that any son of Mars can also rival Lycurgus.

Existing health bodies, national, state and municipal, must be upheld until they can be improved—mark you, not replaced, but improved. We are not and never will be successful radicals and the whole tendency of our people for two thousand years has been, not toward elimination and substitution, but toward amendment, first, last and always.

To this conservative trait we owe the stability of northern European and American governments and the vast sense of security resident in the breast of every citizen of these governments. Fifteen hundred years intervene between the Saxon *gau* and the New England town, and yet they are the same in all essentials. The villager has simply improved his individual status and the primal idea of all having a hand in the government remains the same.

Very slight, indeed, are the formal differences between the ideal health organizations and the existing bodies. A little change in the manner of making appointments; a little better training of personnel; a little fuller understanding by the public of what we seek; a little more care in filling the posts of gradually receding incompetents with well-drilled men, and the end is attained without friction or ill-feeling.

This way, as I see it, lies our destiny. Shall we follow it? Shall we make preventive medicine a very real power in the profession? Or shall we be content to consider it a side issue?

Original Articles

THE LIMITATIONS IN PUBLIC HEALTH ADMINISTRATION *

HENRY BIXBY HEMENWAY, A.M., M.D.
EVANSTON, ILL.

A potent cause of unsatisfactory results in public health work is found in the vague ideas often entertained among officials, private physicians and the people generally, relative to the powers and duties of health departments. There is often a clearer perception of the object to be attained than of the means to that end. Very few physicians have more than a hazy notion of the science of sanitation. Education in this line is emphatically lacking, and the importance of the subject is little recognized. The Council on Medical Education of the American Medical Association recommended that out of a course of 4,100 hours only 120, or less than 3 per cent., should be divided between this great subject and medical economics and medical jurisprudence. Considering the fact that this council speaks for the leading American medical schools, it is not strange that we find great ignorance among our professional brethren as to the objects to be sought, and the steps to be taken, in sanitation.

There is inherent in the Anglo-Saxon mind a love of liberty; but liberty is not license. Professor Burgess, in his "Comparative Constitutional Law," sets forth clearly and at some length the fact that true liberty is only found under a constitutional government, and that for this purpose government exists. Thus, in the fourteenth amendment to the Constitution of the United States, we find the provision that no state shall "deprive any person of life, liberty or property, without due process of law." Under military law this provision may be laid aside. Sometimes it is true that for sanitary reasons, as in the presence of a pestilence, it may be necessary to declare martial law, but such a process must be reserved for extreme necessity. It is repugnant to all our institutions. Arbitrary or autocratic methods in health administration arouse an opposition which defeats the object sought. The health official is not a despot, but a servant, whose duty it is to preserve the health of the community in conformity with the laws which have been properly enacted.

---

*Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

In the United States the national government has only such powers as were conferred on it by the people of the several states. Essentially the state is supreme, and there are reserved to it by the tenth amendment to the Constitution all those powers not given to the nation or prohibited by the Constitution to the state. The only authority of a sanitary nature which the nation has must be found in the regulation of commerce. We frequently hear the suggestion that the national government ought to pass a law regulating the practice of medicine, for example, so that the requirements might be uniform in all parts of the land; and to make transfers from state to state less troublesome. Though such a law might be desirable, as a practical fact it is at present impossible, for the simple reason that Congress has no power to pass such an act.

A similar problem is found in the preservation of interstate rivers and lakes from pollution. The people might, especially in the presence of an epidemic, permit the government to step in actively to purify a river, but its legal power might be very questionable. This power must rest somewhere; if not in the national government then it remains with the state. Through its power to regulate commerce the government has a degree of authority over navigable waters. It is, therefore, constantly spending large sums for the deepening of rivers and harbors. This leads to another practical problem of power and limitations. An act for the deepening of rivers usually provides that it be done by contract at the least possible expense to the government. The contractors who have been dredging the Chicago River have been dumping the slime and filth from the bottom of the river into the lake, and the water-supply of the city has been thereby threatened with contamination. The War Department, which has charge of the dredging, can not order the dredgings taken further into the lake, for that would increase the cost of the work. No national statute is violated by dumping near the cribs. Neither has the national government the power to pass such a law. It may, however, have inserted into the appropriation bill a provision governing such contracts, so that the contractor may be paid for the extra transportation, and under such conditions dumping near a crib might be a violation of contract.

There is another way by which this object may be gained. By the acts creating the Territory of Illinois and the State of Illinois, and by the constitutions of the state, the eastern boundary of the northern part of the state is the middle of Lake Michigan. By the law of the state (Chapter 34, Section 3) also, the jurisdiction of Cook and Lake counties extends to the midle of the lake, whereas (Chapter 24, Section 71) the jurisdiction of a city like Chicago extends over the waters of the lake only three miles beyond the limits of the city. Although Section 256 of Chapter 24 of the Revised Statutes of Illinois provides that: "The jurisdiction of such city, town or village to prevent or punish any pollution or injury to the stream or source of water for the supply of such water works shall extend ten miles beyond the corporate limits," we have the opinion of Attorney-General John W. Griggs to the following effect: "While an ordinance of the city of Chicago may, as to all persons subject to its jurisdiction, forbid the deposit of any heavy substance in the waters of Lake Michigan within eight miles of the shore in front of that city, it can not control or limit the power of Congress over the navigable waters of the United States, nor dictate where it shall or where it shall not deposit, within such waters, material removed in the improvement of one of its harbors." It will be noticed that Mr. Griggs' opinion is relative to the power of a city, not of a state. The power of the state is not there discussed. It is quite true, as Mr. Griggs states, that the proper "remedy is by appeal to the good sense, discretion, and fairness of the Secretary" (of War), for pacific measures may often attain the desired result more quickly than by a resort to force. As a basis of appeal, however, the law of the state should be more potent than that of the city, and in the light of such cases as Wilson vs. Blackbird Creek Company (2 Peters, 245) it would seem that in case of necessity action by the state might prevail in the courts, even against the national powers.

The Blackbird Creek Company, being so authorized by the State of Delaware, constructed a dam by which the navigation of the stream was interrupted. The primary object was to reclaim a marsh, thus increasing the value of the property, and to improve the health of the inhabitants. Wilson was the owner of a sloop, licensed and enrolled under United States statutes. He injured the dam, and, being sued by the company, he denied the right of the state thus to interfere with commerce. Chief Justice Marshall delivered the opinion sustaining the power of the state, although it "stops a navigable creek and must be supposed to abridge the rights of those who have been accustomed to use it." In Gilman vs. Philadelphia (3 Wallace's Rep., 713) the opinion of Mr. Justice Clifford, Wayne and Davis concurring, refers approvingly to the Blackbird Creek case, saying that it "treated the erection of the dam as one adapted to reclaim the adjacent marshes and as essential to the public health, and sustained the constitutionality of the law authorizing the erection, on the ground that was within the reserved police powers of the state." This expression is the more significant for the reason that this dissenting minority held that the Blackbird Creek case did not apply in the Philadelphia bridge case, because there was no question of sanitation involved in the erection of a bridge across the Schuylkill river. The majority of the court had upheld the powers of the state to erect such a bridge, basing their action on the Blackbird Creek decision.

When two constructions of a statute are possible, one of which is constitutional and the other not, we are bound to choose that which is. An act of Congress which refers to a regulation of commerce may be construed in harmony with the sanitary powers of the state; or, in line with the opinion of Mr. Griggs, above mentioned, as against, and superior to such sanitary control by the state. In the latter case Congress would in reality assume jurisdiction over sanitary matters which it does not possess. Such a construction would make the act unconstitutional, on the ground that Congress had exceeded its authority. We are forced, therefore, to reject a construction which makes the power to regulate commerce necessarily paramount to state sanitary statutes, and to accept the view that the state still has sanitary jurisdiction over the officers and agents of the national government.

Neither county nor state may do anything which would interfere with navigation without the consent of the War Department, but it is their manifest duty to protect their citizens by passing and enforcing suitable laws for the preservation of the purity of the water-supply, and such laws the nation is bound to respect.

> So far as the decisions of the ultimate tribunal on constitutional interpretation now stand, the following propositions seem to be established: (1) The several states have power to pass laws regulating the internal police of their own territories, which territories include navigable rivers and harbors, as well as unnavigable streams, and the land itself. These police measures . . . are simply a part of the general system by which each state endeavors to protect the good morals, lives, health, persons and property of its inhabitants.[1]

It is generally admitted that quarantine regulations are controlled by the states. I have found no case to the contrary. As Pomeroy says:[1]

> This entire class of statutes establishing police regulations is within the purview of state legislation, whether Congress has legislated for the same or similar purposes or not. Among them may be mentioned laws establishing quarantine, licensing and controlling pilots. . . .

In the case of Gibbons vs. Ogden (9 Wheaton's Rep., 203) Chief Justice Marshall says of inspection laws:

> They form a portion of that immense mass of legislation which embraces everything within the territory of a state not surrendered to the general government; all which can be most advantageously exercised by the states themselves. Inspection laws, quarantine laws, health laws of every description, . . . are component parts of this mass. No direct general power over these objects is granted to Congress; and, consequently, they remain subject to state legislation.

So in Barbier vs. Connoly (U. S. Reports, 2 Peters, 102) we find the police power of the state to include "to prescribe regulations to promote the health, peace, morals, education and good order of the people."

The authority of the states to pass health laws, as in opposition to the power of Congress to regulate commerce, has been discussed in many cases before the Supreme Court of the United States, and whenever it has appeared that the statutes or regulations have been really in the interest of health the authority of the state has been sustained. Several statutes have been declared unconstitutional on the ground that, though nominally health regulations, they were not so in fact, but they were restrictions of commerce. Such was the ruling in the Railroad Company vs. Husen, 5 Otto, 465, in which the State of Missouri attempted to exclude cattle from certain other states, and in the Passenger cases (7 How., 283); yet in these the sanitary power of the states was recognized. In the Passenger cases Mr. Justice McLean said: "In giving the commercial power to Congress the states did not part with that power of self-preservation which must be inherent in every organized community" (p. 400). On the other hand, in Smith vs. St. Louis and Southwestern Railway Co., 181 U. S., p. 248, which, like the Husen case, referred to the quarantine of cattle, it was held that "quarantine law as construed and applied in this case is not in conflict with the Constitution of the United States. The prevention of disease is the essence of a quarantine law. Such law is directed not only to the actually diseased, but to what has become exposed to disease." In Morgan's Steamship Co. vs. Louisiana Board of Health, 118 U. S., p. 455, we find:

> The system of quarantine laws is a rightful exercise of the police power for the protection of health which is not forbidden by the Constitution of the United States. While some of the rules of that system may amount to regulations of commerce with foreign nations or among the states, though not so designed, they belong to that class which the states may establish until Congress acts in the matter, by covering the same ground or forbidding the states. Congress, so far from doing either of these things has, by the act of 1799 (Chap. 53 Rev. Stat.) and previous laws, and by the recent act of 1878 (20 stat. 37) adopted the laws of the states on that subject, and forbidden all interference with their enforcement.

In Jacobson vs. Massachusetts (197 U. S., 11) Mr. Justice Harlan says on page 25:

> The authority of the state to enact this statute is to be referred to what is commonly called the police power—a power which the state did not surrender when becoming a member of the union under the Constitution. Although this court has refrained from any attempt to define the limits of that power, yet it has distinctly recognized the authority of a state to enact quarantine laws and health laws of every description, indeed all laws that relate to matters completely within its territory, and which do not by their necessary operation affect the people of other states.

This power was upheld, even though it stopped navigation, as in Leovy vs. United States (177 U. S., p. 621), in which the right to erect a dike was upheld for public health, and in Manigault vs. Springs (199 U. S., p. 473), with reference to a dam on Kinlock Creek, and in *Compagnie Francaise de Navigation à Vapeur* vs. Louisiana State Board of Health (186 U. S., p. 380) a steamship company was forbidden to land its passengers at certain points in the State of Louisiana then under quarantine, although those passengers were not diseased, nor had they been exposed to disease, so far as was shown, and though they had sailed from European ports, in accordance with treaties made between the United States and European nations.

If the sanitary authority rests primarily in the states, does it not necessarily follow that it is the duty of the states to enact and enforce such laws and regulations as shall be best fitted to preserve the lives and health of the citizens? Does not a neglect to do so expose the state to a liability for damages? The object of laws is not the punishment of offenders, but the preservation of the persons and property of the citizens from injury. After an epidemic has despoiled a community, the state can not restore lives lost, or compensate for sickness. The duty of the state is to prevent the epidemic. Methods must change with increase of knowledge. Modern sanitary science is giving many aids for the control of disease far more efficient than the ancient quarantine. Health administrators may rightly be expected to keep informed, and to communicate to legislative bodies the knowledge of these advar [illegible] for their application. The special [illegible] ch branch of government must be recognized by all.

It must be remembered that the state has no authority to pass any retroactive law, or one which will impair a contract. In the case of dredging contracts already existing which have been based on the right to dump in the vicinity of the cribs, a new law prohibiting such dumping might be held as an impairment of contract. In the case in question, however, Illinois has a statute in the criminal code (Chapter 38, Section 202) providing that "whoever wilfully and maliciously defiles, corrupts or makes impure any spring, or other source of water, or reservoir . . . or aids and abets in any such trespass, shall be fined not exceeding $1,000, or confined in the county jail not exceeding one year." If that statute applies here, such dumping is illegal, and, therefore, a contract based on a presupposed violation of this statute would not be impaired by making the penalty greater, or more clearly stating the prohibition.

It is proper here to ask the question whether or not the discharge of sewers into the lake is not also a violation of this same statute, providing they are so located as to contaminate the water supply of the city. Probably this question may be answered only by a court decision.

---

[1] Pomeroy: Constitutional Law, Sect. 329.

Just as the national government may not enact legislation further than the people of the individual states have granted authority, so cities, towns, villages and counties are restricted to the powers expressly given by the states. The unit is the state, not the city. Still we sometimes hear it stated that the city has complete power to control sanitation within its limits. The specific powers of a city may vary in different states, but the general statement is the same for all. Again, turning to Illinois for an example, we find a clear statement in the case of Jenkins vs. Board of Education. The relator, Louise Jenkins, was refused admission to the John Fiske School in Chicago because she had not been vaccinated, the board of education basing its refusal on an ordinance of the City of Chicago. In its decision the court says: "Not only has the legislature never prescribed vaccination as a condition to the enjoyment of the legal right to attend public schools, but they have never conferred on cities the power to do so," and again in the same decision: "The health commissioner is a purely ministerial officer and has no legislative powers whatever."

American governmental bodies are based on the triple system, legislative, executive and judicial. These should be distinct. The wording of the different constitutions vary, but the theory is the same in all. That of Illinois, for example, provides that "no person, or collection of persons, being one of these departments, shall exercise any power properly belonging to either of the others."

Health departments are executive in their character, and they should be so restricted in their operations. It is true that in many states a city or village council may be given the duties and authority of a board of health. Such provision is no exception to the general independence of the three branches. The council is legislative whether in or out of the board of health, and the health officer or commissioner is the executive.

Sanitary laws, like those of other nature, should be passed by legislative bodies; state boards of health, so far as I know, have nowhere in this country legislative powers. They may make rules and regulations for carrying into effect the statutes enacted, but such rules have not the standing or the permanence of statutes, and it is a mistake to attempt to depend on such regulations when a statute can be secured. To give uniformity and strength, so far as possible the sanitary statutes should be passed by the state legislature, rather than depend on the enactments of cities. The state statutes should require a certain form of health administration in every city of the state. That makes it possible without delay to communicate with the proper official. An illustration of what is not advisable may be found in the Illinois statutes on this point. There is no provision for compelling the appointment of either a city commissioner of health or board of health, but either are permitted. Neither is there any statement of the qualification for such officials.

If the requirement that contagious diseases should be reported depends on municipal enactment there is immediate confusion. One city requires whooping-cough reported, but not tuberculosis, and there may be a variation also in other requirements. Such laws should be passed by the state, specifically mentioning each disease to be reported, and stating by whom, to whom and when such reports should be made. It is unfortunate that a very large proportion of practitioners do not yet realize that it is as important to report malaria and typhoid fever as it is to restrict smallpox. The determining what diseases should be reported should not be left to the individual judgment of a health officer or to the uncertain ruling of a court. Statistics to be valuable must be on a uniform basis and complete. The personal equation must be eliminated as much as possible.

There is a great difference between a mandate and a request. It is unfair to the practitioner to require him to comply with a rule which he may not easily find. He may be expected to comply with state statutes, but he should not be punished for failure to comply with a ruling of a health officer, or of a court, when such rulings are not easily within his knowledge. On the other hand, for due reason clearly stated, a health officer may request the reporting of a disease not mentioned in the statute, and the request would be generally complied with by the citizens if it were reasonable. Such reports would form a basis for study, and by proving their value the request might pave the way for the statute.

Statutes to be effective must be definite. While it may be necessary sometimes to leave something to the judgment of the executive, the essential requirements must be clearly stated. Suppose the statute simply requires the reporting of "infectious diseases," without mentioning their names. A physician failing to report malaria might deny its infectious character, and legally his opinion is as good as that of the health official. Only a court decision could settle the dispute. On the other hand, it may be left to the health official to determine to some degree the form of the report. His form may include a statement of water- and milk-supply, school attended and other important data, but unless such data are mentioned in the statute both official and practitioner must recognize that the giving of such information is largely an act of courtesy on the part of the reporter.

Not only is an executive health official denied legislative powers, but he is prohibited from acting in a judicial character. He may, and must, often decide questions of interpretation, but his decision is personal, not official. He may not legally determine what diseases shall be reported. Neither may he judicially decide that any statute is being violated. He may prosecute or begin action, but only a court may give a judicial decision.

According to the statutes of some states, the state board of health also has charge of licensure for medical practice. I am not aware of any judicial decision on this point, but it seems that such a provision is unconstitutional on the ground that boards of health are essentially executive, while the work of license boards is judicial, and entirely foreign to the work of a health department. The license board passes judgment on the standing of a medical school, or the educational and moral qualifications of a candidate, basing its action on the evidence presented. Prosecutions for violations of practice laws might properly be brought by a health department, but when the prosecutions are brought by the same body which issues the license the condition easily gives rise to a suspicion of legalized blackmailing.

One great limitation to all health work is ignorance. Administration can not advance far beyond popular knowledge. The model department of health must be primarily an educator. It must educate itself by making original investigations. Others may equally well make bacteriologic experiments, but health officials have a peculiar advantage for the collection and analysis of statistics. Since statistics form a very large portion of the foundation of public sanitation, it follows that to be a good statistician is a most important qualification for a health official. Then, too, there are certain problems which attract the attention of the sanitarian, which may totally escape the consideration of others. For example: Though plankton (pelagic flora and fauna, distinguished from coast and bottom forms) has been studied in its relation to fish culture, its sanitary relationship is not as yet known. It is quite likely that some forms may be pathogenetic either directly or by their effect on food fish. On the other hand, potamoplankton especially may prove a most important aid in sewage destruction.

The health department must also educate physicians and the laity to an appreciation of the known facts of sanitation, and to arouse a popular interest in the subject. With such a sympathetic interest it will be much more easy to secure suitable legislation, and to enforce the laws without unnecessary friction. On the other hand, when the legislation is far in advance of the popular education the executive must encounter great opposition in its enforcement. It is the lack of this sympathetic assistance which sometimes causes great annoyance. Frequent cases of a contagious disease occur, without an apparent connecting link, because many of the cases are unreported. A limitation here is caused by the unwillingness of people to submit to quarantine. Perhaps that unwillingness arises from financial necessity. The problem suggested is very largely sociologic, and the question to be answered is, how far the community is justified in establishing quarantine. Has the community a moral right to quarantine a family, unless it provides for the support of the family during the time?

A question as to the rights of an individual who is apparently healthy forms another limitation to the health official. Statutes should be passed giving the health official a right to make an examination of the person and discharges of a supposed disease-carrier, typhoid or diphtheria, for example, and to restrict the liberty of all such persons, prohibiting them especially from all occupations in which they would handle food materials, as in dairies, bakeries, restaurants, etc.

Sometimes a health official assumes authority which he does not possesss. Sanitary regulations relative to destruction of rats and insects should be based on statutes, but time may be saved sometimes by issuing an order unsupported by the law. It rarely is necessary to declare martial law. In the absence of specific laws it is usually safer to depend on moral suasion than to strain the force of authority. The facts should be clearly stated to the people that the responsibility for conditions and lack of statutory aid may be placed where it properly belongs.

While it is within the province of a health department to treat disease, it is questionable whether or not such treatment should go beyond protection against the spread of the disease. Unnecessary interference with private business arouses an opposition which does much to limit the usefulness of a health department. Physicians hesitate to report cases if they are to be deprived of the care of their patrons.

In a similar manner it is often necessary that the community should furnish free antitoxin for the purpose of restricting disease. If, however, the antitoxin is given free to all, the legitimate business of manufacturers and merchants is stifled. It is difficult to see any more excuse for supplying free antitoxin to all than for supplying clothing or bread for all.

It is not presumed that the foregoing is a complete discussion of the subject, but it is intended rather as a suggestive outline, to call attention to a much-neglected feature of our work. No reference is made to the limitations in school inspection, that great field for preventive medicine which must largely depend on wise legislation for authority. Neither have we called attention to the physical limitations, dependent on the nature of the soil and its former occupation, or on other conditions largely beyond control. It is a simple matter to construct a rat-proof town, but San Francisco has found it no easy task to exterminate those vermin from old buildings poorly constructed. And there is another great limitation so common as to be well recognized—that of finance. If we have not enough to do all we should like, we are obliged to select that which is most necessary.

1243 Chicago Avenue.

ABSTRACT OF DISCUSSION

Dr. J. W. Clemmer, Columbus, Ohio: This paper treats of fundamental principles in sanitary administration, and nothing could be of more importance in the public health service. At bottom this service rests on legal authority. A public sanitarian should know the legal provisions on which to ground public service. Sanitary authority primarily rests on a grant of the state; this grant may delegate authority to local boards of health to create such rules and regulations which on publication will have the force and effect of city ordinances. The state law may be specific in defining sanitary provisions in all matters of public health interests. In Ohio, large and general powers for sanitary administration are conferred on local boards of health. In turn, these boards create sanitary laws or ordinances for the regulation of the public. In this way the state confers not only police powers, but judicial powers on health boards. The Supreme Court of Ohio has recently confirmed the decisions of the lower courts in a case from Cincinnati in which a sanitary official, in carrying out a regulation of the board of health demanding the confiscation and destruction of milk kept for sale above a certain temperature, arrested and successfully prosecuted a dairyman under this regulation. From this it appears that all the courts of Ohio have confirmed a ruling of the health board in a specific matter of public health regulation. Such powers of administration applicable to other affairs give all the authority desired. The constitutionality of such enactment of the legislature, conferring such powers on appointive bodies, may be questioned, but the fact remains that the results of such a law in Ohio are satisfactory.

Trauma and Gastric Ulcer.—W. Oettinger reports in the *Archives des Maladies de l'Appareil Digestif*, iii, 1909, page 61, three cases in which a gastric ulcer developed after a contusion of the epigastric region, and the causal connection he regards as beyond question. He sifts the literature on the subject of ulcer consecutive to external trauma of the stomach region, and calls attention to occult hemorrhages in the stool as an important aid in diagnosis of gastric ulcer. Chemical tests of the stomach functioning in his cases after the trauma showed excessive glandular activity, and the fasting stomach contained a few c.c. up to 90 c.c. of gastric juice, free from admixture of food. This may be due to excess of glandular functioning, transient pyloric spasm or muscular atony, or all combined, and all these factors favor development of an ulcer. Hematemesis may be observed at once after the accident or after several days, or it may not occur, and the major classic symptoms of ulcer, paroxysmal radiating pain, vomiting of food, etc., are not the rule, but the exception, he says, in gastric ulcer. Diagnosis is possible, however, by investigation of the secretory and motor functioning and search for occult blood in the stool, and he expatiates on the importance of an early diagnosis before irreparable destruction of tissue. His patients were men between 28 and 38, and the accidents had occurred while driving or autoing.

MOLLUSCUM CONTAGIOSUM

REPORT OF AN INSTITUTIONAL EPIDEMIC OF FIFTY-NINE CASES*

FRANK CROZER KNOWLES, M.D.
Assistant Dermatologist to the Philadelphia Hospital; Dermatologist to the Northern Dispensary, the Church Home for Children, the St. Vincent's Home, the Baptist Orphanage;
Assistant Dermatologist to the Dispensary
of the Children's Hospital
PHILADELPHIA

The term "molluscum" ("molluscis") was first used as descriptive of a dermatologic condition by Ludwig,[1] in 1739. The word was probably intended as a synonym for "mollis," describing certain soft tumors. Alibert,[2] Biett,[3] Cazenave[4] and Schedel,[5] on the contrary, attribute the origin of the term, used by Bateman,[6] to some resemblance existing between the cutaneous tumors and the knots on the bark of the maple. The disease was first described by Bateman in 1817, who gave a very good clinical description. The nomenclature of dermatology in the earlier days of this science of medicine was exceedingly chaotic. Several cases were reported as molluscum contagiosum shortly after Bateman's communication, but the most of these were, probably, fibroma molluscum. Alibert treated of molluscum contagiosum under the name of "mycosis fungoides." Bazin[7] described the disease under the term of "acne varioliformis." Erasmus Wilson[8] wrote of the condition under the heading of small sebaceous tumors. Duhring,[9] in 1881, used the title of "molluscum sebaceum." Unna in his book, "The Histopathology of the Diseases of the Skin," called the disease "epithelioma contagiosum." The terms employed by the various writers on this subject show the extensive and diverse titles used as descriptive of the condition.

Ever since this disease was first described the contagiousness has been discussed; Stelwagon's excellent paper[10] on the subject, in which are enumerated all the household and institutional epidemics on record, speaks strongly in favor of the contagious theory. Household and family epidemics will not be mentioned in this paper, but all of the institutional cases that have been obtainable will be described in some detail.

INSTITUTIONAL EPIDEMICS ALREADY RECORDED

Caillault's Cases.[11]—A girl, aged 8, was admitted to a hospital ward, with numerous tumors on the face, the eyelids and the shoulders. Fourteen out of the thirty children in the same ward finally became affected.

Ebert's Cases.[12]—A girl, aged 14, was admitted to a hospital with tumors on the face. The disease spread to three children who occupied the nearest beds and who came in contact with the patient and each other.

Liveing's Cases.[13]—Nine cases were observed in a school. A few months after the first case was noticed, the eight other patients were attacked.

Mittendorf's Cases.[14]—An epidemic was seen at a home for children. The disease was introduced by a little girl; an attendant noticed lesions on the eyelids at the time of her admission. A few weeks later several of the other girls developed similar lesions. Three months after the arrival of the first patient at the home, twenty-seven children had the disease. Another epidemic was observed at a nursery and hospital for children. Forty-one of the children were attacked within two years after the first case had been noted.

Jackson's Cases.[15]—A small outbreak occurred in the children's pavilion of a hospital. A week after the first case came under observation, 2 others developed; a week later another appeared; and the next week 2 additional cases—6 in all.

Allen's Cases.[16]—A child, with a few typical lesions on the face, was admitted to an asylum. Forty-two children were attacked by the disease a few months after the first child entered the institution. Five new cases subsequently developed, making a total of forty-seven. Another epidemic was described by Allen, also in a children's hospital. A little girl was brought in with a few characteristic tumors on the face; a boy playmate soon developed lesions of the same type; five other children were attacked by the disease.

Stelwagon's Cases.[10]—The first series, consisting of four cases, was seen in a children's hospital. The disease was discovered in one of the crippled infants, and a short time afterward three other patients, in the same ward, were attacked. The second epidemic occurred in a home for children; there were thirteen cases in all among about a hundred children. The third outbreak was noted in the last-named institution about a year later, the former patients having been cured. It consisted of twelve cases.

Tommasoli's Cases.[17]—This epidemic consisted of fifty-six cases in a children's asylum in the city of Sienna.

Graham's Cases.[18]—A little girl was brought to a home for infants with mollusca on the face. Two months later four children developed the disease. The lesions continued to appear on the other children; in four years' time fifteen cases were noted.

AUTHOR'S CASES

During the last year 59 cases of molluscum contagiosum have been seen in St. Vincent's Home out of about 350 children.

Sex.—Thirty of the patients were girls and the other twenty-nine were boys.

Age.—Five of the cases occurred at 7 years of age; 7 at 6 years; 11 at 5 years; 18 at 4 years; 14 at 3 years; and the 4 remaining cases at the age of 2 years.

Location of Lesions.—More than one area was involved in 27 of the cases. The eyelids were attacked in 22 cases; the chin in 16; the cheeks, right, left or both were involved in 11 cases; the forehead was the area of predilection in 11; the nose in 9; the cutaneous surface of the lip in 5 cases; the neck, anterior surface, in 5; the posterior surface of the neck in 3 cases; the left ear in 2; the dorsal surface of the right hand in 4 cases; the middle of the back in 1 case; and in 1 case, the left thigh was the site of attack. In 1 case, the vermilion border of the lower lip was involved by two small, pinhead-sized lesions. Two of the patients reported by Allen also had mollusca on the mucous membrane of the lip. A severe conjunctivitis was produced in one of the cases by a molluscum on the edge of the eyelid causing friction. Similar instances have been reported by Steffen[19] and also by Muetze.[20]

Number of Lesions.—One lesion was present in 19 of the cases; two in 12 cases; three also in 12 cases; four mollusca in 4 cases; five lesions in 2 other cases; six in 4 cases; 1 patient had seven lesions; and in 5 children there were, on each, twelve mollusca. The lesions were mostly from small to large pinhead in size; one molluscum was, however, pedunculated and cherry-size.

EXPERIMENTAL INOCULATION

Whenever the opportunity offers experimental inoculation should be tried, in order to determine, if possible, the incubation period of the disease. Several authors (Retzius,[21] Paterson,[22] Vidal,[23] Stanziale,[24] Pick,[25] Haab,[26] and Nobel[27]) have reported favorable results. Several others (Stelwagon,[10] Allen[16]) have been unsuccessful in the attempt.

Retzius reported a successful inoculation on himself. A small quantity of the molluscum material was rubbed into the upper chest; this area was protected by a watch-glass. A pinhead-sized lesion appeared four to five months after this experiment; the growth progressively increased in size during the next three months. The lesion then gradually disappeared. Microscopic examinations of the pressed-out contents were corroborative of the clinical diagnosis.

Paterson, after several attempts, finally succeeded. The contents of the tumor were inserted into the follicles, in a tender part of the skin; such as the angles of the mouth, axillæ, mammæ, etc.

Vidal recorded a successful result, Pantry, one of his assistants, performing the experiment. A positive result was determined in three months.

Stanziale's experimental inoculation also had a successful termination. The substance of the molluscum was rubbed into the sound skin of the inner surface of the arm and forearm; three months later a hempseed-sized lesion developed. Forty days later this tumor had become pea-sized.

Pick, of Prague, was extremely successful in his experiments; nine out of twelve inoculations succeeded. The skin over Scarpa's triangle, in a boy of 11 and a girl of 9, was used in the inoculation. The twelve inoculations were made just within the epidermis. The lesions did not begin to develop until the tenth week; two weeks afterward they were excised, and were found to correspond microscopically with molluscum.

Haab succeeded in inoculating himself, after rubbing the contents of a freshly extirpated lesion into the skin of the forearm. Nothing was noticed for six months, when a characteristic hempseed-sized lesion developed, resembling, clinically and microscopically, a typical molluscum growth.

Nobel's reported favorable result was performed on a patient already attacked by the disease, one of the lesions on the patient acting as the inoculating material. Characteristic lesions did not develop for nine weeks.

Inoculation experiments were attempted in two children, each aged 4, the one a boy and the other a girl. These two children had not been exposed to the disease. In the first case the inoculation was made on Nov. 8, 1908; a small area on the right upper arm was excoriated by a scalpel until oozing of lymph occurred; the contents of a molluscum from one of the affected patients was then rubbed in, antiseptic precautions being observed. Five weeks later a small, conical, yellowish, elevated lesion was noted in the inoculated area; this lesion looked typical of a beginning molluscum. In a few weeks' time, however, the lesion dried up and disappeared. No other phenomenon has occurred in this area.

The second subject was inoculated on Nov. 24, 1908. Two small areas were abraded on the outer surface of the upper arm; the contents of the molluscum was rubbed into one of these; a few drops of a sterile salt solution mixed with some of the contents of a molluscum lesion was rubbed into the other. Unfortunately the arm became somewhat infected and the result has been absolutely negative. The areas inoculated were covered by vaccination shields. The incubation period of the disease can not be stated because the successful results so far obtained have varied between a few weeks and many months. The incubation period, from the time of admission of a child into the home until the disease was acquired, was approximately, in several cases, a year and one-half.

PATHOLOGY

The microscopic picture of the pathologic changes that occur in this disease is quite characteristic, with the lobulated appearance, the fibrous capsule, and the diagnostic molluscum bodies. The origin of the growth, and particularly the molluscum bodies, has been, and still is, a much discussed and unsettled question. The subject has been so fully described in the excellent paper[28] of C. J. White and W. H. Robey, Jr., that only a few of the important points will be emphasized here.

Engel,[29] in 1844, regarded the tumor as an enlarged sebaceous gland; Rokintansky,[30] and also Hebra,[31] some years later, agreed with Engel. In 1865 Virchow[32] stated that the new growth was a lobulated, glandular epithelioma arising from the hair follicle. Retzius stated that the tumor did not rise from the hair follicle, but owed its origin entirely to the epidermis. Boeck[33] denied the sebaceous origin of the new growth, because fat could not be detected in its cells.

White considered that the source of the growth was the rete layer. Crocker[34] believed in the follicular origin of the tumor. Benda[35] stated that in some cases the tumor arose in the hair follicle. Caspary[36] believed that the tumor had its origin in the rete cells. Patterson, in 1841, was the first to mention the so-called molluscum corpuscles or bodies. MacCallum[37] limits the term "molluscum corpuscle" to the peculiar body inside of the epithelial cell. Kaposi[38] beieved that the peculiar molluscum bodies arose from the transformation of cell protoplasm. Vidal inferred from the jelly-like translucency of the bodies that they were the product of a colloid degeneration. Geber[39] sketched the evolution from the rete cells. Unna[40] believed that the bodies were only the result of colloid or hyaline degeneration of the prickle cells.

C. J. White, in the most elaborate paper written recently on this subject, considers that the bodies are simply keratin, identical with the horny layer, except in the shape of the individual cells. He states that the growth arises from the rete, and that there is an extraordinary metamorphosis of rete cells into normal keratin. Several biopsies were made in these cases; the microscope proved the clinical diagnosis.

BACTERIOLOGY AND CULTURAL EXPERIMENTS

Angelucci,[41] in 1881, described a bacterium, the *Bacterium lepogenum*, which, he maintained, was the cause of the tumor. Neisser,[42] in 1882, denied this and put forward the theory that the cause of the tumor was a gregarin and asserted that the peculiar bodies were the shells of these organisms. Graham[18] stated that he had found a micrococcus in his cases, which grew on potato and in bouillon, produced fermentation in milk, and was stained by Gram and Gabbet's methods. Robey, after extensive cultural experiments, came to the conclusion that the organism found was the *Staphylococcus epidermidis albus* of Welch, the normal inhabitant of the deeper layers of the skin.

Cultural experiments were made in these cases and two organisms were found. The first was a non-motile bacterium, size 0.5 to 1.0 by 1.0 to 2.0 microns, aerobic and facultative anaerobic. It grows abundantly at either room temperature or at 37.5 centigrade. It was negative to the Gram test. All of the differential tests were carried out and the organism was classed as the *Bacterium aerogenes*. The organism was probably present because of some slight contamination at the time of making the molluscum cultures. The second was a round, slightly oval coccus, divided in all planes, about 0.8 microns in diameter; Gram's method gave a positive result. Careful experiments were carried out on all culture media, and numerous tests were employed to determine the proper classification. This organism apparently is the *Micrococcus salivarius;* it was isolated by Biondi from the saliva. It resembles markedly the *Micrococcus epidermidis albus*, but differs from it in one chief way, in its activity regarding gelatin; the *Micrococcus albus* liquefies it in about two to three days, the *salivarius* not at all. These two organisms resemble each other so closely that it is only fair to suppose that they are in some way related; possibly two forms of the same micrococcus.

It is to be hoped that the etiologic factors of the disease will be elucidated, and that the pathologic origin of the growth and of the so-called molluscum bodies will be positively determined.

SUMMARY

Molloscum contagiosum usually attacks the face, in a great majority of the cases on, or in close proximity to, the eyelids. Children are more susceptible to the disease than adults.

It is very difficult to explain the present or other epidemics on any other theory except that the disease is contagious.

The cause of the disease is, unfortunately, still to be determined; although a micro-organism, usually a coccus, has been found in a few cases.

The incubation period is undetermined; from the experiments so far carried out, from a few weeks to many months.

The skin apparently does not have to be broken for the infection to occur, but this point is still undecided.

In closing I wish to express my thanks to Dr. Thomas Cope, pathologist to the St. Vincent's Home, for the careful cultural experiments; to Dr. C. Y. White, former pathologist to the home, for pathologic sections, and to Dr. Kolmer, resident physician in the same institution, for inoculation tests.

332 South Seventeenth Street.

ABSTRACT OF DISCUSSION

Dr. George Pernet, London, Eng.: One point not mentioned is that molluscum contagiosum may be found in certain birds, such as pigeons and buntings. In one instance two women contracted the disease from a pet pigeon. One case was in the practice of an ophthalmologist, and was recorded by him. The patient was in the habit of fondling the pigeon, and suffered much from the disease, especially about the eyelids. Since that time, when these patients come to me, I always inquire whether they have handled birds of this sort. I find that curetting the lesions with a sharp fenestrated curette is one of the readiest methods of getting rid of them, instead of splitting them up.

Dr. Louis A. Duhring, Philadelphia: The photographs that I saw did not show the usual formation of the tumors, in that there was no distinctly defined umbilication. It is well known that this umbilication is not always manifest, and apparently it was absent in some of these tumors. I have seen cases of this disease for many years in my own city and elsewhere, and I am always on the lookout for it in the hospitals with which I am connected, but I have found that it is a rare disease outside of asylums and institutions. Notwithstanding the facts relating to contagion, I have never been convinced of the contagiousness of the disease, and the many experiments that have been made still seem to leave that an open question. Its epidemic character is, of course, to be recognized, especially in institutions. The treatment of molluscum contagiosum may be made extremely simple. Perhaps the easiest method is to touch the lesions with a drop of acetic or trichloracetic acid, or to incise and express the contents.

The pathology of this affection, as described by Dr Knowles, is in accord with the studies that have been reported by Dr. White of Boston. I could never see that the disease was parasitic, rather it seemed to be due to elaborate changes in the epidermis, which have been so well described by Dr. White and by others. The affection has also been observed in birds and certain animals.

I think that records of epidemics of the kind narrated should be reported, and in the course of time we shall have much valuable material from which to draw conclusions. The question of the possible contagious character of the disease is one of importance, and one about which we ought to express ourselves if we have had any experience touching on that subject.

Dr. Marcus Haase, Memphis: I recall one case in an English boy, 19 years old, who had a linear group of three lesions on the anterior aspect of one leg. Having had my attention called to the fact that this disease might be transmitted through birds, I questioned him along that line, but he said he had never handled birds.

Dr. William A. Pusey, Chicago: As a student, I was taught to expect molluscom contagiosum as a common affection, but I have found it rare. I certainly see in Chicago ten cases of blastomycosis, for example, to one case of molluscum contagiosum.

Dr. F. C. Knowles, Philadelphia: In regard to the occurrence of this affection in birds, and various other phases of the subject, I did not take the time to refer to them, as the literature is very extensive, and I had to stick to the subject under discussion. In the pictures that I passed around, it was my endeavor to bring out the umbilication of the lesions. Most of the lesions were absolutely typical in every way, including the umbilication.

St. Vincent's Home, where the epidemic reported by Dr. Stelwagon occurred, is a sister institution to the one referred to in my paper, and the children are sent there as they grow older. It was apparently a continuation of the same epidemic. As a rule, I see about ten or fifteen of these cases every year in the hospitals with which I am connected, but during the past year I have seen over 100 cases, including the 59 reported in this paper. In Dr. Hartzell's service at the University of Pennsylvania Hospital, I have had an opportunity of seeing, during the last few months, an epidemic of over 30 cases; the students in the college department were attacked. This is the largest number I have seen in one year.

THE COMPARATIVE VALUE OF THE INTERNAL ADMINISTRATION, INUNCTIONS AND INJECTION METHOD OF ADMINISTERING MERCURY IN THE TREATMENT OF SYPHILIS *

EUGENE CARSON HAY, M.D.
HOT SPRINGS, ARK.

In presenting this article I realize the magnitude of the subject and my inability to do it full justice in the time allotted to me. Hence I shall endeavor to discuss the merits of each method impartially and estimate their comparative value, more from my own personal experience in their employment than from the opinions of authors, and I shall quote only when I deem it necessary, as such information any of us can obtain by consulting text-books.

Mercury still stands the premier of all remedies in the treatment of syphilis, and in the light of recent research its position has been reinforced and greatly strengthened. The brilliant work of Schaudinn, Metchnikoff, Neisser and Wassermann has proved that mercury is still our chief remedy, and that the reasoning of all our great clinicians has been correct in regard to its action.

The serum treatment is still in its infancy, and even if one is developed that will cause a more rapid disappearance of syphilitic manifestations than mercury it will require years to prove its superiority and to establish it as a remedy on which we can rely.

INTERNAL ADMINISTRATION OF MERCURY

The ingestion method, or mercury administered by mouth, is one of the oldest methods, and one used more generally by the profession than any other. I fully realize the storm of criticism that may follow my condemnation of this treatment, especially since it is the one favored by our greatest syphilographers.

Fournier calls it the "true method of the treatment of syphilis," and I cheerfully acknowledge him the greatest living authority on syphilis to-day. He prefers internal treatment to all other methods as routine work, and his writings, in addition to Ricord's, are responsible, I believe, for the popularity of the protoiodid pill—the hydrargyri *iodidum flavum of the Pharmacopeia*. In this country White, Keyes and Taylor are also partial to the protoiodid for routine treatment.

Jonathan Hutchinson considers his gray powder with opium as superior to all other forms of administration.

Keyes, in advocating the internal treatment, prefers the protoiodid pill, to be administered according to his method, which he calls his "tonic treatment," and a great many American physicians have adopted his system.

It is right here, though, that I presume to take issue with these eminent authors, and say that the internal, inunction and injection methods should be employed in the treatment of every case of syphilis; or the internal and inunction combined; or the internal and injection combined; depending on the condition of the patient, his surroundings, etc., as to which is the most advantageous or convenient under the circumstances as they exist. I am opposed to depending on the internal administration alone, as in my experience its action is so feeble and so slow on the syphilitic manifestations, disappointing and discouraging to the patient, on account of slow progress. Its irritating effect on the gums, as it produces stomatitis much earlier than when using either of the older methods; its irritating effect on the stomach and bowels, especially when anything like an adequate dose is given; its uncertain action, being the slowest of all the methods in appearing in the urine; and the frequent outcropping of symptoms while under its influence, have led me to depend on it only when the patient is free from all manifestations of syphilis, and it is desired to keep him slightly under the influence of mercury, as a matter of precaution, when he is being allowed to rest between the periods of his heavier courses of medication. As a rule, the gums will become inflamed, and gastrointestinal symptoms develop long before any material improvement has occurred in the symptoms of the patient, and in most of the grave tertiary lesions that I see the patient gives a history of indifferent treatment or a two or three years' course of internal medication. At least 95 per cent. of the patients with secondary syphilis who consult me have been on pill treatment from one to six months. They generally show numerous symptoms in the form of mucous patches, secondary rashes, sore throat, or some of the other symptoms coincident with the secondary stage. It is not unusual, inaddition, that their gums are sore and inflamed from mercury, and the treatment has been so impotent that they come to the springs for relief, even against the advice of their home physicians. Immediate change for the better is noticed as soon as they are put on the inunctions or injections of mercury, and within a period of three or four weeks as a rule they are free from all manifestations and apparently fully restored to health. It is such cases as these that create numerous converts to the Hot Springs treatment. A large percentage do not remain long enough, return to their homes, and shortly resume internal treatment, and it is not unusual for me to receive letters from them in a period of from two to three months, stating that recurrent secondaries have developed. Now, to my mind, any treatment that will allow symptoms to develop when under its influence (of course, excluding malignant syphilis) is inadequate and should not be depended on exclusively. In some cases of old tertiary lues, in which there is pronounced anemia and cachexia, I have seen beautiful results from internal administration of mercury, combined with iodid of potassium, the old "mixed treatment," so called; but in the early secondary period its action is too slow and in the presence of any grave lesion it is absolutely impotent. In my locality I see numerous cases of tertiary syphilis, involving the nervous system, and a great number of them give histories of three years' internal treatment, especially those that have developed parasyphilitic conditions. These clinical pictures, with which I am so often confronted, have naturally caused me to consider this method of very feeble therapeutic value. The objections of some that it is not scientific because we can not tell how much is absorbed can also be said against the inunction method; but this objection is of very little importance, it seems to me, as it is of minor consequence how little or how much mercury is absorbed, just so we get the therapeutic result; no two people absorb mercury alike; no stereotyped dose can be exactly laid down for all cases. The doses must be varied according to the individual, and it is of little consequence only so that we are careful not to overmercurialize our patient.

When giving mercury by mouth, I prefer a pill containing biniodid of mercury and the iodids of arsenic and gold; it is non-irritating and has been productive of good results. Another pill to which I am very partial is one recommended by Dr. Bernheim, of Philadelphia, in a paper read before the Mississippi Valley Medical Association in 1898, and which he calls "pill enteric." His formula, which I have slightly modified, contains:

---

* Read in the Section on Dermatology of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

½ grain metallic mercury,
½ grain hydrated wool fat,
½ grain purified ox-gall.

This pill produces less gastrointestinal disturbance than any I have ever used and is as potent in its effect as any of the salts of mercury.

INUNCTIONS OF MERCURY

This is the oldest method of administering mercury, and was employed as far back as the fifteenth century. The description by Fournier of the barbarous manner in which it was applied in those days engendered a prejudice against mercury that reaches down to the present day in the minds of the laity, and is fostered and kept alive by patent-medicine vendors and quacks. It is the ideal way of administering mercury, and would be far superior in routine treatment to any other method we possess if its application were not disagreeable and associated with so many objections.

First, the most important objection, I consider, is that it betrays the patient's secret, and if he is married or living with his family it is practically impossible to administer it without detection. A great many object to it because it is more or less filthy apparently, especially when the mercury cycle is used, and if great care is not exercised in protecting the skin it frequently produces a severe dermatitis. I have seen patients in whom the treatment was absolutely interdicted on this account, the skin being so tender that one application would produce a most violent dermatitis. In one unique case of mine a single inunction of mercury produced a severe edema of the side on which the rub was applied. The rub was applied to the outer surface of the right thigh; the next day the patient's right leg, arm, scrotum and penis were intensely red and edematous.

Patients at home object to the treatment, not only on account of its publicity, but because one can not feel very clean when being constantly anointed every day on different parts of their anatomy, and wearing a suit of underwear stained with the ointment. A very important factor in securing results from this method is to have the ointment properly applied: it should be applied by a trained rubber or masseur. This is the reason that in most cases this treatment is left to be administered at the different thermal resorts that are noted for the treatment of lues on this continent and in Europe; this is why our results are superior to those obtained at home, when the ointment is applied by the patient.

Among the advantages of the inunction treatment I will first mention that it is not painful and it is free from danger. It is potent and intense, and the stomach is left free for other medication. As it is quick and potent in its action, it produces immediate and rapid improvement of the patient, and the disappearance of all syphilitic manifestations. A very marked change for the better is produced within a few days. It does not affect the gums nearly so quickly as the internal administration, but when stomatitis does occur, if the mouth has not been frequently inspected and kept clean, it is liable to be more severe and to last longer. Occasionally early in the course, but generally after several weeks' rubbing, the patient will suddenly develop a mercurial intoxication in the form of acute enterocolitis, with severe griping pains and profuse diarrhea, and the stools may contain a little blood. This condition can generally be relieved within forty-eight hours; the patient can resume his treatment without any further discomfort, and he will generally finish his course with no recurrence.

Frequently these attacks are brought on from indiscretion in diet, and are not due to mercurial poisoning.

In my eighteen years' experience at Hot Springs, and in treating over six thousand cases of syphilis in private practice, I have employed inunctions extensively, and the longer I use them the more partial I have become to them and convinced of their merit; but there is one defect which occasionally causes failure in the treatment and which I have observed a great many times. It is not due to any fault of the method, but to the idiosyncrasy of the patient. There are some patients who, on account of the peculiar texture of the skin, do not absorb mercury. You may rub them over a long period and not witness any response to treatment by improvement of their symptoms, the physiologic action of the drug, or manifestation of mercury in their urine. These patients, of course, if one changes to injections, will immediately respond and show marked signs of improvement. Such cases, I think, are frequently mistaken by physicians, who believe the phenomenon to be a demonstration of the superiority of injections over inunctions; and, of course, in these particular cases, injections are superior. But it does not demonstrate that injections are better for all, as the fault is to be found in the resistance of the patient's skin, and not in the method.

I could cite a great number of such cases from my case books, but I do not care to take up space with case records. The only place I have seen this fact mentioned in literature is in the new work, "System of Syphilis,[1]" in the chapter on the treatment by inunctions, etc., in which the statement is made that in some cases no mercury was eliminated by the urine, although the skin had been thoroughly anointed, so that it seems as though some skins were impervious to this method of administration.

Ehrmann first drew attention to this important fact in connection with the elimination of mercury after inunctions. He showed a patient at the dermatologic congress held at Vienna in 1901 whose urine was free from mercury, although he had been rubbed with mercurial ointment on twenty occasions.

Mracek, at the same meeting, told of a patient who was still covered with the maculopapular syphilid, although he had received four hundred inunctions of mercury. In spite of this energetic treatment, he never had any mercury in the urine, and the syphilitic signs actually increased while he was under treatment. The technic of this method of administering mercury is very important in promoting good results; also the quality of the ointment used; I have used a great variety of ointments, and prefer Squibb's 50 per cent. ointment.

At Aix-la-Chapelle, the mercury cycle is used; that is, different portions of the body are selected every day for the rubbings until the whole surface is anointed. This is the method generally in vogue throughout this country by physicians in our large cities. The Hot Springs method is confined to applying mercury on the back, and sometimes on the hips, and outer surface of the thighs. It was first instituted at the Springs forty years ago, and physicians practicing there still employ it, and have never seen any advantage or reason for making a change. Our results are as good and gratifying, and the physiologic effect just as rapid as when the other method is used, and it has the advantage of being much cleaner, pleasanter, and more agreeable to the patient.

---

[1] System of Syphilis. Edited by Power and Murphy, Oxford Med. Pub. Co., London, Chapter 13, Vol. II.

Our technic is as follows: After a warm bath the patient sits astride of a chair, and the attendant spreads the ointment on the back, using a rubber mitt to protect his hand. The ointment is thus rubbed in with a long, sweeping, circular motion, the attendant exercising a firm pressure, but not sufficient to produce too much warmth, as hard rubbing produces irritation. After he has finished, a thin gauze athletic shirt is pulled down over the surface to protect the other undergarments, or else a mercurial pad is used, which is impervious, and is much preferred by many patients. This pad was recently invented by Dr. Randolph Brunson, of Hot Springs, for the purpose of obtaining quicker constitutional results, as the outer covering of the pad is made of an impervious fabric, which produces a slight moisture and softening of the skin, and thereby promotes a more rapid absorption of the ointment. If the pad is used, it is worn constantly throughout the entire course. If the mercury shirt is used, it is changed every ten days or two weeks, as the patient keeps it on constantly, not removing it even when he retires. He gets constant absorption from contact, as considerable mercury becomes deposited on the shirt. Before the inunction is applied the attendant washes the back thoroughly with some good antiseptic solution. The one I prefer is the 1 to 2000 biniodid of mercury, or equal parts of liquor antisepticus U. S. P., and saturated solution of boric acid. This latter formula is very soothing, as there is always plenty of infection on the surface of the skin, and sterilization of the back will add largely to the prevention of any irritation; any hairy portion of the back should be shaved before a course of rubs is instituted. If the patient seems to have a specially irritable skin, in addition, I have the back oiled with a solution of ichthyol and oil of sweet almond. This does not interfere with the action of the mercury, and generally keeps the back in excellent condition.

Now as to the comparative value and potency of the inunction and injection method: From my experience, I am convinced that the inunctions are just as powerful in their action as any of the soluble preparations of mercury, and in some cases much more so; also the effect of the inunctions is much more lasting, and recurrent symptoms do not occur near as early as they do after a course of soluble injections. I have been using injections for ten years, and during that period have had ample opportunity to compare the two methods, as during this time about 75 per cent. of my luetic cases were on the inunctions and 25 per cent. on injections. With few exceptions, I have not been able to see any advantage soluble injections have over the inunctions. The symptoms are not relieved any faster, and, if anything, the improvement in the inunction cases has been more rapid. In addition, the injections are generally more or less painful. To some patients they do not seem to cause any discomfort, while others will rebel against them bitterly. There seems to be a great difference in patients' susceptibility to the pain-producing property of mercury. I have yet to use an injection, containing mercury of sufficient quantity to be of benefit, which would not cause more or less pain. I have had a great number of patients under my care who have recently been to a northern resort in this country where the soluble injections of mercury are largely used. After being conducted through a course of inunctions, they invariably become disciples of the inunction treatment. Patients who do not thrive on the inunctions and improve more rapidly on injections of soluble mercury do so, as I said before, on account of lack of absorption, and still there are others that improve on account of constitutional idiosyncrasy, and I have frequently observed the reverse occur, and had them improve rapidly on the inunctions when injections had failed. There is a great difference in patients' susceptibility to mercury; some require an enormous amount to produce the desired result, while others require very little. One patient, who was suffering with a large gumma on his forehead, had been rubbing for six weeks before coming under my care, and taking large doses of iodid of potassium. The treatment made no impression on the tumor, but, in fact, it was growing larger, and he showed no symptoms of mercurialization. I gave him thirty-six injections of salicylate of mercury, one grain each, every other day, with complete disappearance of the tumor, and still no evidence of mercurial depression or tenderness of the gums appeared. I allowed him to rest two months, and gave him twenty injections of modified gray oil, one grain each. At the expiration of this course, his gums became slightly inflamed, or "touched'" as we express it. I saw him eighteen months later and he was in excellent health.

Another patient whom I had under my care four years ago, with cerebral syphilis, took 136 inunctions and twenty-six injections of one-fourth grain each, of succinimid of mercury, coincident with the rubs. At no time was the course interrupted, nor did he show any pronounced symptoms of mercurialization; as to the merits of this treatment in his case I recently received a letter from him, stating that he is in perfect health. These cases, of course, are rare, while now, at the other extreme, we occasionally encounter patients who can not stand mercury at all, even when their condition indicates that they are sadly in need of it. I have seen one inunction of mercury produce a severe mercurial intoxication; in another case two inunctions produced similar results. Frequently these poor unfortunates have a tendency to malignant syphilis, and can not tolerate specific treatment and show no response to it; they tax our ability to the limit.

The theory that was advanced in Germany a few years ago, that no absorption occurred from the rubbing of mercury, but that the medicament was taken in entirely by inhalation, has always appeared to me absurd. This has been proved a fallacy by the experiment of shaving the back of a rabbit and rubbing the mercury in the exposed part of the skin; a section of the skin was then examined under the microscope, and globules of mercury were found in the sebaceous and sudorific glands.

Likewise, we all know that rubbers would be susceptible to mercurial poisoning if this theory was correct, as they are exposed to the so-called fumes while constantly rubbing it. I know bath-house attendants at the Springs who have been rubbing mercury for thirty years, and have never shown any signs of mercurial poisoning, nor have I ever heard of one. I have a man in the rubbing department of my office who has been rubbing on an average of from ten to twenty patients a day for ten years; the room is kept at a temperature of from 80 to 85 F., and he has never shown any symptoms of mercurialization in the slightest degree.

INJECTION METHOD

The injection method of administering mercury, according to Fournier, was first "introduced by Hebra in 1864, but it did not really enter into practice until after the publication of Lewin in 1867." It grew into popularity much more rapidly on the continent of Europe than in America, and I think the writings of Taylor and J. William White in Morrow's "System of Genitourinary Diseases and Syphilis," condemning it, had considerable to do with retarding its adoption by Americans, and subduing our enthusiasm; especially as White's article contained letters from a large number of our most prominent specialists in those days, and they all condemned it as inferior and dangerous. In the last twelve or fourteen years, it has rapidly grown into favor in this country, especially injections of the soluble salts of mercury. Hundreds of papers have been written on the subject, and I fear some writers have allowed their enthusiasm to warp their better or more matured judgment. The marvelous claims for it by some I consider very much overdrawn and I do not consider it a treatment that should be adopted in all cases, as advocated by some.

If a great many of these same zealous enthusiasts had had the same experience with the inunctions, I firmly believe that their opinions would be very much modified, and of more value. The injection method has many attractive advantages: first, it is clean; it is secretive; it absolutely conceals the patient's condition from every one but his physician; but the large volume of advantages that are claimed for it by the numerous advocates would fill several chapters.

Colonel Lambkin, in "System of Syphilis," vol. ii, gives as a brief list of the most important points to consider as I have found. They are as follows:

1. It is convenient to the patient.
2. It insures the patient's getting regular treatment.
3. It leaves the stomach free for the reception of other medicines.
4. It insures more accurate doses.
5. The absorption of mercury is much more certain.
6. It does not interfere with the gastrointestinal system.
7. There is less chance of toxic symptoms, especially of stomatitis.
8. Both therapeutic intensity and physiologic effect are much more marked when the mercury is introduced by this method than by others.
9. I will add that some writers have stated that we get a greater amount of effect from a smaller amount of mercury than when using any other method.

I will briefly analyze the various claims: Nos. 1, 2 and 3 I admit and pass on without further discussion, only to say that the same can be said about inunctions.

4. The dose may be more accurate; but what advantage is this, if no two persons require the same dose? And frequently the dose has to be changed at different periods in the same patient.

5. The absorption of mercury is much more certain. This will depend, though, on its not becoming incapsulated, as it frequently does. Often we see patients, especially those who have been taking injections of the soluble salts of mercury, with their buttocks a mass of nodules even a year or so after they have received the injections; that these nodosities all contain mercury is beautifully illustrated in the two cases cited by Fournier. I have also seen these nodules suddenly absorbed and producing very sore gums.

6. As to the claim that it does not interfere with the gastrointestinal system, this is a grave mistake, as I have seen very severe mercurial intoxication produced from the injections, and the fatal cases that had been reported from the insoluble salts generally show marked disturbance of the gastrointestinal tract.

7. As to there being less chance of toxic symptoms, this is also a grave error. A number of deaths have been reported from injections of insoluble preparations of mercury. Dr. Fuller, in his article on the "Salicylate of Mercury,[2]" speaks about the possibility of producing an oil embolism that may manifest alarming symptoms, though not fatal.

Fournier relates numerous deaths that have occurred from injections of calomel, and I presume all have seen Lessère's recent report of the number of deaths and accidents that have occurred from injections of insoluble salts and gray oil.

Bartsch, of Breslau, has recently published several cases of poisoning with fatal results, two of which are especially interesting; one patient, a young woman of 24, died from four injections of a 10 per cent. solution of salicylate of mercury. Another, a woman of 40, died after four injections of calomel; both patients had severe diarrhea and mercurial colitis.

As to the injections being less liable to produce stomatitis, when the latter does occur, it is generally much more severe and lasts longer than when using the other methods.

8. I admit that the therapeutic intensity and physiologic effect is much more marked and lasting when the insoluble preparations are given, but not so when the soluble are given, as they are inferior to inunctions in most cases.

9. As to securing the greatest effect with the smallest amount of mercury, I consider this of minor importance. It seems to me a matter of very little consequence how much mercury you use, so long as it does not injure your patient, and he improves while under its administration.

The soluble preparations I have used are the succinimid, bichlorid, biniodid, sozoiodolate, albuminate, benzoate, and cyanid. I prefer the cyanid and the succinimid, as they are the least painful. The bichlorid I consider superior to them all, but it is so painful and prone to nodulation that a great many patients will not submit to the treatment. I have modified and greatly reduced the pain from injections of bichlorid by the following formula:

℞.	gm. or c.c.	
Bichlorid of mercury	|5	gr. viii
Phenol (carbolic acid)	|5	m. viii
Physiologic salt solution	31|	℥i

The dose is from fifteen to thirty minims (1 to 2 c.c.) every other day. This is my original formula, although it has been appropriated as original by two writers in different parts of this country, but they received the formula indirectly from me. There is no danger from the carbolic acid in this preparation, and it greatly reduces the pain of the injection.

INSOLUBLE PREPARATIONS

This is the most intense and potent method we have of administering mercury, but, as it is not free from danger, it should not be adopted as a routine and used without discrimination and care; hence, it should be reserved for selected cases, especially those in which it is desired to produce a profound mercurial impression. The one that ranks at the head of them all, I presume, is calomel, but with it I have never had any experience, although I was deeply impressed with the article read before this section last year by Dr. Klotz. I have been deterred from its use by the literature on the subject, as the majority admit that it is very painful, besides being the most dangerous. I have never had a case in which I deemed it necessary to resort to its use. My experience has been confined to the emulsion of salicylate in 10 per cent. solution of liquid petrolatum, as advised by Fuller and Gottheil. I used this preparation in a number of cases for about one year, and had some very excellent results, one in particular I have mentioned above, but, on account of the volume of the injection, and a number of patients complaining of it being painful, I changed to the modified gray oil, as suggested to me by Dr. Heidingsfeld. The original gray oil, or oleum cinereum, as invented by Lang, I had previously tried and discontinued, likewise on account of the great pain it produced.

---

[2] Med. Rec., New York.

About three years ago Dr. Heidingsfeld gave me his formula, which was a modification of Lang's, and consisted of pure hydrated wool fat and bidistilled dental mercury, equal parts by weight, making a 50 per cent. ointment, of which one minim approximately represented one-half grain metallic mercury. His previous modification of Lang's oil I had tried, and stated to him that I found it very painful. In this previous formula he used liquid petrolatum and also sterilized his wool fat; he had discovered that if he did not sterilize the wool fat and depended on the mercury to render the oil sterile it caused very little discomfort and was almost painless. Sterilizing the wool fat causes some chemical change with which I am not familiar, but it is a clinical fact that it does render the injections much more painful. I have been using this preparation now for the last three years, and am much pleased with its results and its powerful action on syphilitic lesions; very few patients have ever complained of pain from the injection. Some will complain of pain and soreness a day or so after the first two injections are given. After that their hips seem to become inured and cause them very little discomfort. The dose is from two or three minims, as suggested by Dr. Heidingsfeld.

Dr. L. E. Schmitt, of Chicago, uses as high as five minims, but I prefer the small dose, and give the injections more frequently. This oil being so thick (the appellation "gray ointment" would be more descriptive), there is practically no danger of producing an embolism, and the small quantity injected is an important factor, I think, in rendering it less painful. A preparation used in England is called "mercurial cream." With this, liquid paraffin is added to the base, as in Lang's latest formula; this is used largely in the British army, and admitted, by the writers who advocate its use, to be very painful.

Colonel Lambkin has modified the formula, and uses palmitin as a base, adding camphoric acid and absolute creosote to render it painless and sterile. He uses the same combination with calomel injections, and says that it renders the injections of both absolutely painless.

His description of his experiences with these preparations is, indeed, very attractive, and I intend giving them a trial.

I have administered over six hundred injections of Heidingsfeld's modified gray oil, and have had only two superficial abscesses, both in women with fleshy hips. They were caused by withdrawing the needle too soon and allowing a thin column of mercury to follow the needle into the subcutaneous tissue. In addition, the needle was not sufficiently long to deposit the mercury in the muscular tissue.

The technic of these injections is very important. In the first place, the needle must be long enough to insert the oil well into the muscles, as it is a very stiff ointment; after inserting the needle, considerable pressure must be exerted to expel the oil into the tissues. Likewise, the needle should be allowed to remain at rest before it is withdrawn, fully twenty to thirty seconds, so that the mercury has ceased oozing from the end of the needle, thus avoiding the accident I spoke of above; if any mercury is deposited immediately beneath the skin, it is liable to form a very sore and painful nodule that may possibly terminate in a superficial abscess. Great surgical care and cleanliness must always be carried out in giving these injections.

I employ this preparation in all cases that have failed to respond to the soluble injections or inunctions, in cases in which I desire a quick and intense action of mercury in the presence of all serious lesions, especially of the nervous system, when desiring to give the therapeutic test, and in cases of patients who object to frequent visits to the office. Injections are given every other day, every third day, twice a week, or once a week, depending on the mercurial energy I wish to exert. My results have proved to me that it is the most intense and desirable method of administering mercury in severe cases, and a treatment to which a patient rarely, if ever, objects. Cases in which the other methods have failed will respond to these injections, and my results, as a rule, have been all that I could desire, and most gratifying to the patient. The method is not nearly so liable to produce mercurial intoxication as are the soluble injections, but there is one important factor to keep in mind always: At the first suggestion of tenderness of the gums or any other toxic symptom, the treatment must be stopped, as there still remains considerable mercury in the tissues, and if you are not very careful you are likely to have very severe stomatitis with pronounced physical and nervous prostration. I have had the gums become inflamed a month or six weeks, and in one case two months, after the course of injections had been finished, E. L. Keyes has made the same observation.

SUMMARY

Now, to recapitulate as briefly as I can, in comparing the three methods:

As stated before, I consider that all methods should be combined at different periods during a full course of treatment. A course of treatment in the early inception of syphilis, I think, should start either with inunctions or injections and be followed by internal medication, instead of the pill or internal treatment being given first, and followed later by injections and rubs, as advised by most modern text-books. The brilliant results to be obtained in the prevention of future accidents in any case, I think, are to be accomplished in the first year's treatment, and we should attack the disease energetically, and when the system is being flooded with the syphilitic virus. The more rapidly we can overwhelm and cause the extinction of the spirochete, with a treatment that is not injurious to the system, the better is our selection. Hence I have formulated the following routine to be pursued in cases of syphilis as they ordinarily run:

First Year.—Two courses of either inunctions or injections, covering a period of two months each; after each course of treatment a month's rest should be allowed and then internal medication two months during the interim up to within a month before resuming the second course, whether inunctions or injections, making four months' rubs, four months' internal treatment, four months' rest.

Second Year.—Two courses of rubs or injections six weeks each; two courses of internal treatment, eight weeks each; two courses of rest, six weeks each, and two of four weeks each, making a total of three months' heavy rubs or injections, four months' pills, and five months' rest.

Third Year.—Treatment every other month, alternating between the internal and more intense methods.

Fourth Year.—Six weeks of inunctions or injections.

Fifth Year.—Four to six weeks of inunctions or injections. The above treatment is given in tabular form:

TABLE OF COURSE OF TREATMENT FOR FIVE YEARS

First year.

2 months' inunctions or injections.
1 month's rest,
2 months' internal treatment,
1 month's rest,
2 months' inunctions or injections,
1 month's rest,
2 months' internal treatment,
1 month's rest,
Giving 8 months' treatment, and 4 months' rest.

Second Year.

6 weeks' inunctions or injections,
8 weeks' rest,
8 weeks' internal treatment,
4 weeks' rest,
6 weeks' inunctions or injections,
8 weeks' rest,
8 weeks' internal treatment,
4 weeks' rest,
Giving total, second year, 7 months' treatment, 5 months' rest.

Third year.

1 month inunctions or injections,
1 month rest,
1 month internal treatment,
1 month rest, continuing so throughout the entire year, alternating from internal to injections or rubs
Thus giving the total during the third year of 6 months' treatment, and 6 months' rest.

Fourth year.

6 weeks' inunctions or injections.

Fifth year.

4 to 6 weeks' inunctions or injections.

Then one course of treatment of one month each, for the next five years, thus carrying our patient up to or through the parasyphilitic stage. I do not contend that every patient absolutely needs this protracted treatment; no doubt, a good number escape, and live to a ripe old age, after a very indifferent course, of one or two years' treatment following infection. Undoubtedly some recover spontaneously, but there is a large percentage of those who do not enjoy such luck, as my home is a Mecca for so many of these unfortunates; I am constantly confronted with numerous cases of early neglect and insufficient treatment.

Fournier states that at least 50 per cent. of tertiary lesions involve the nervous system, and this does not include all the parasyphilitic lesions. Hence, I think it better to treat a little too long than to stop one day too soon. I have patients who have been under my care for fifteen years who visit the Springs annually and take a course of three weeks of inunctions. Most of them have shown no signs of syphilis for ten or twelve years. Still they do this as a matter of precaution; the treatment seems to do them no harm and they enjoy excellent health; as the cure of syphilis is so uncertain, I feel more secure under these precautions and the patient feels likewise. I am a positive believer in the cure of syphilis, but I make this statement with qualifications, as I believe that, with few exceptions, the organism of every patient who has ever had syphilis is indelibly stamped with it for life; and that a proper course of three to five years' treatment following the infection will cure the average patient, provided he leads a proper life, but that there is always that apprehension that in the future, if some intercurrent trouble develops, that will create *the locus minoris resistentiæ,* his old malady may manifest itself in the form of a grave or serious accident.

In my experience I have seen it return thirty, thirty-eight and forty years after infection; during the intervals, the patients enjoyed excellent health and responded rapidly to treatment, which proved the diagnosis.

The important points which I wish to emphasize in this paper are:

All three methods should be used in treating any case of lues, as previously described.

When first instituting treatment after infection, either inunctions or injections should be employed, followed by internal medication, instead of treatment with pills, first followed by more heroic methods, as advised by most of the leading writers.

The inunctions, from my experience and observation, on an average, are superior to the soluble injections, and more lasting in their effects.

The insoluble salts are too intense and profound to be employed in routine, and should be held in reserve for rebellious cases and for cases in which rapid and pronounced mercurialization is desired.

Finally, the long course of treatment I have advised should be pursued in all cases.

The six cardinal points in the therapeutics of syphilis are to keep a close observation of the weight, kidneys, bowels, stomach, gums and nervous system; especially the latter, as some patients will never manifest any evidence of mercury in the form of stomatitis, and the first evidence you have is a profound and acute nervous prostration.

102 Exchange street.

ABSTRACT OF DISCUSSION

Dr. William S. Gottheil, New York: I advocate a conservative eclecticism in the treatment of syphilis. We should never forget that when we introduce mercury into the human system we are incorporating a substance that is poisonous, and that may have untoward and unexpected effects. Death has occurred from administration of mercury in any form, by ingestion and by inunction; it has occurred from injections of soluble as well as of insoluble preparations of this drug. Injections of gray oil have been responsible for more accidents than any other preparation. I am not prepared to say that this is because it is more dangerous than the others; perhaps it is because it has been more largely used.

There is a distinct reaction after the injections; the metallic antitoxin acts exactly like the organic diphtheria antitoxin in this respect. I have studied this more especially in the case of physicians who were under treatment. There are chills, malaise, pains in the limbs, and a temperature that may rise to 104 F. and over. This reaction may be so severe as to constitute a valid contraindication to the mode of administration. There are also other contraindications. Some patients are so thin and have such small gluteal muscles that the injury of the injection causes them too much trouble; and occasionally we meet one so very stout that the longest needle will not reach through the layers of fat into the center of the muscle mass, and painful indurations result. I have found, however, that women stand the injections remarkably well, provided that a sufficiently long needle is used; and I always keep some on hand for the purpose.

Dr. W. B. Trimble, New York City: I thought Dr. Gottheil advocated the use of the injection treatment, above all others, and as a routine measure in every case, I disagree with this view, as I do not think it the method of election in every case of syphilis. If it were necessary to select one form of treatment to the exclusion of all others, I do not think I would hesitate in choosing the inunction plan. The soluble preparations that I usually employ are the succinimid and the benzoate.

Dr. Alexander S. Wolf, St. Louis: It appears to be a comfortable and convenient arrangement for both physician and patient to have a nurse or an attendant rub the blue ointment into the skin of the patient, but such a luxury can be had only by the wealthy. Such a procedure, however, is not rational, and for the rich as the poor we must insist on self-inunction treatment as the one which under necessary instructions for the patient—and in this regard our young generation of physicians must be instructed thoroughly in the school—will alone be of benefit. While the poor patient will abide by our directions without any further deliberation, the well-to-do patient who has heard about inunctions carried out by a nurse, must be enlightened as to the necessity and rationality of self-rubbing. You need only to impress on his mind that it is better for his health and the result of the treatment, if a good deal of the ointment will remain in the skin of his own hand than in the leather of the nurse's glove.

Dr. Louis E. Schmidt, Chicago: In discussing this subject of the comparative value of the different methods of treating syphilis, we should do so in connection with our present knowledge of serum reaction. I have had about 60 cases of syphilis in which practically the same line of treatment has been carried out, mostly by the injection method with gray oil. I want to bring out the result of the Wassermann test in these cases. In some cases, the test was negative after only eighteen months of treatment, while others gave a marked reaction after four or five years of treatment. I have had patients under my observation and treatment for three, four and five years, and still the test is positive. What am I to do in such cases? Am I to continue vigorous treatment for ten years or more if the reaction continues positive, and in those cases that give a negative reaction after only eighteen months of treatment, can treatment be discontinued or pursued less vigorously? I believe the test should be repeated every six months, and if it remains negative, continue to leave the patient untreated. However, as the test is still so new, I am inclined to believe that a mild mixed treatment should be kept up.

Dr. E. C. Hay, Hot Springs, Ark.: One point I would like to emphasize is that the insoluble injections should not be repeated too rapidly, in order to avoid the possibility of mercurial stasis, as alarming or even fatal symptoms may develop if not detected in time from a sudden absorption of a large quantity of mercury. This condition can generally be recognized by keeping a close watch over the urine for the elimination of mercury. In regard to the inunction method, I am not in favor of having the patients rub each other. In my experience, it has been better to employ a trained rubber for that purpose, one who can do the work more thoroughly than the patients could do it for themselves.

Municipal Playgrounds.—Playgrounds, places for the youngsters to play and develop their young lungs by exercise, are becoming one of the big items in the budget of a city. Chicago, for instance, has spent eleven million dollars on a system of playgrounds and recreation centers, containing outdoor and indoor gymnasiums, swimming pools, wading pools, shower baths, swings, slides, ball fields and rooms for lectures and social meetings. New standards have been set up in neighborhoods that knew them not, and the benefit is accounted so great that the cost of $2.00 per $1,000 assessed valuation of the property benefited is regarded as an ideal investment of the city's income.—*Hygiene and Physical Education.*

INOCULATIONS OF POLYVALENT STAPHYLOCOCCIC SUSPENSIONS IN STAPHYLOCOCCIC INFECTIONS OF THE SKIN *

HENRY ROCKWELL VARNEY, M.D.
Clinical Professor and Lecturer on Dermatology and Syphilology in the Detroit College of Medicine; Dermatologist to Harper Hospital
DETROIT

Now that time has allowed the smoke of enthusiasm to clear away, we should be able to take an accurate reckoning of the value of artificial immunization of patients with staphylococcic infections of the skin.

Two years ago, before this Section, I reported a series of staphylococcic infections of the skin treated by bacterial inoculations. The conclusions at that time were not unlike those of other investigators along this line of treatment. Autogenous suspensions were found more efficient than monovalent stock suspensions, and inoculations guided by opsonic estimations were found more effectual than those that were not so guided.

Owing to the time consumed in isolating the invading organism and standardizing the suspensions, and the difficulties in making opsonic estimations, opsonic therapy has evoked criticism. The purport of this paper, then, is to discuss the simplifications which assist in placing opsonic therapy on a practical basis. So much progress has been made over our previous knowledge that we are now able to obtain as good results, in selected cases, with polyvalent stock suspensions as with the autogenous. Laborious opsonic estimations are unnecessary as a guide to reinoculations. Experience has proved to me that inoculations of a polyvalent stock suspension, made at intervals indicated by clinical symptoms, produce as good results as when controlled by opsonic indices.

For some time bacteriologists have noted minute differences between cultures of the same species obtained from different sources, although the morphology of the organism shows the typical form on ordinary culture media. A suspension, then, made from a number of strains of the same organism, obtained from various patients suffering from the same disease, is the stock suspension employed. The object of this is to embody the varying properties of a number of strains.

Polyvalent suspensions of staphylococcic strains have been and are being used by many investigators, but, to my knowledge, no large number of strains obtained from the same disease has been employed. My polyvalent suspensions have contained no less than twenty different strains, which have been increased to forty by mixing two or more suspensions. These strains are kept growing slowly, at room temperature, in darkness, and are transferred as infrequently as possible to keep them alive. By this method the virulence of the strain is probably less lowered than might be the case if the strain was frequently transferred. New strains are occasionally being added which give varying ages to the suspensions as well as varying virulence. Such a suspension is as easily prepared and standardized as an autogenous one, and retains its activity, as far as can be determined clinically, for at least six months. Here, then, we have a stock suspension which is ever ready and can be used when the patient first appears, with a saving of days of time over the method of preparing autogenous bacterial suspensions.

---

* Read in the Section on Dermatology of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

From comparisons of opsonic indices, in a large number of like infections taken in the laboratory prior to using stock suspensions, we are given further valuable knowledge, not only in estimating the size of the dose to administer, but when to reinoculate. The dose of the first inoculation should be of sufficient size to cause only a slight languor, which means a four to eight hours' negative phase after the inoculation. From 100 to 150 millions is the appropriate initial dose, varying as clinical indications denote. In the immunization of animals toward a given toxin, the dose given must be of gradually increasing strength, to a certain standard, the frequency and size of the dose to be governed by the temperature of the animal and other clinical manifestations, and later by potency tests. The same is true of human artificial immunization with bacterial suspension, the doses varying in size and intervals. Within six times twenty-four hours after the initial dose, the patient's resistance, as proved by opsonic estimations, will have dropped after its positive phase to within nearly what it was when the first dose was administered. Then the second dose should be given, which should be from 200 to 250 millions, and the third from 300 to 400 millions. It is seldom necessary to increase the dose to more than 600 millions. The spacing of the first three doses six days apart (six times twenty-four hours) is of importance, and further doses should be given as clinical manifestations indicate. One of the first indications of a lowered resistance and recurrence is a tenderness in the already healed scar, as in boils.

The rebellious types of the following diseases are those to be considered: furunculosis and carbuncle, impetigo contagiosa, sycosis staphylogenes, and pustular acne. In selecting from this group of diseases, we are considering only the rebellious ones, thereby excluding the possibility of spontaneous recovery, consequently putting this therapeutic measure to the crucial test.

What is more annoying than the persistently recurring lesion in what is termed the chronic "boiler," or the sycosis condition which presents itself with a history of years of existence? The patient who returns almost annually, usually during February or March, with a multiple furunculosis has a lowered resistance to staphylococcic infection. We have heretofore reasoned that the condition of such a patient was below normal or he would not be afflicted with such infections. Our medical advice has been governed by such suppositions, and tonics, diet and specific medications, the action of which has never been clearly known, have been prescribed. We had no accurate means of determining the patient's resistance to the infection, or whether our treatment raised his resistance, until Sir A. E. Wright published his most ingenious technic, by the application of which we are able artificially to immunize patients by bacterial inoculations. The further proof that the patient's resistance is not only low during such infection but in the process of artificial immunization, lies in the fact that the patient's resistance shows a prompt rise, as indicated by laboratory indices which are confirmed clinically. The lowered resistance of the patient may not be due wholly to deficiencies in the blood substances or lack of opsonins, but partially to abnormal development or lack of tonicity of the skin structure. General lowered resistance to the staphylococcic family, due to constitutional diseases, will not be considered.

The predisposing qualities of such skin structures to infection must be considered and corrected, or the raising of the patient's resistance will often fail to cure.

Many abnormal conditions in the skin structure predispose to a more easy access of this type of infection into the deeper structures of the skin; for example, the thin, oily skin with the gaping sebaceous ducts not only allows easy entrance of the organisms, but such a skin supplies them with an abundance of food in the excess sebaceous material. The walling-off of such an infected area is Nature's means of preventing systemic infection. This process in the infection of the carbuncle or boil is so thorough that the infected area must necrose in order to rid itself of the infection. This process of defense not only practically stops leucocytosis, but prevents the toxins from entering the blood stream, except in limited quantity, which results in the formation of protective substances and only partial immunization. Protective substances are not generated in sufficient quantities to prevent reinoculation; hence the continuance of the infection. The toxins of such an infection must enter the blood stream in safe quantities in order that protective substances may be elaborated to the degree of immunization. While the natural forces of resistance are spending their best efforts in walling off the infection, unable to produce immunizing substances from lack of specific toxic material, our assistance in artificial immunization is of unquestionable value at this time, which is demonstrated clinically.

One can readily see the utter uselessness of attempting to raise the patient's resistance to a given organism when the protective substances or leucocytes are unable to reach the organisms because of the stagnation of circulation in the area of infection. The absolute necessity for other therapeutic means here presents itself to the more successful management and cure of this type of infection. The drawing off of such stagnant fluid by excision and evacuation of the furuncle or carbuncle and the application of heat, or Bier's hyperemia, cupping to encourage bleeding, is advisable. Such means not only draw off the stagnant infected blood and lymph, but produce increased circulation of blood and lymph through the infected area. At this time the assistance brought about by a general raising of the blood resistance may be effected by bacterial inoculations.

In no other staphylococcic infections of the skin have there been such uniformly gratifying results as in multiple furunculosis and carbuncles. This method of treatment has a scientific basis and is rapidly replacing the older methods. It has been possible, in a number of instances, to compare the efficiency of the polyvalent suspensions with that of autogenous suspensions, observations being assisted by patients, who were physicians. Rarely has a new lesion developed after the first inoculation has been administered. A partially developed lesion can often be dwarfed, and within forty-eight hours all pain and discomfort to the patient will have subsided.

In order to ascertain just what percentage of the cases were recurrent, I recently reviewed the histories for the last two years of patients given polyvalent suspensions: I was surprised to find that there had been only three recurrences out of twenty-eight cases of multiple furunculosis. It was also of interest to note that the three patients who suffered recurrences were those to whom no more than two inoculations had been administered. Undoubtedly, only partial immunization had been effected. Previous to this treatment, at least 90 per cent. of these cases had been the chronic recurrent type, and for a period of two years there have been no recurrences of cases who were given four or more inoculations.

Comparing our knowledge of immunization brought about in other infectious diseases, at least four inoculations seem necessary to insure against recurrence.

It is important to instruct the patients when inoculations are given to take precautions against fatigue. The negative phase will then be less pronounced, and the positive phase prolonged. The beneficial effects of inoculations can be completely destroyed by prolonging the negative phase by fatigue, alcoholism, menstruation, or any intemperate indulgence, and new lesions may develop.

CONCLUSIONS

Polyvalent staphylococcic stock suspensions administered in appropriate doses have a decided therapeutic value in a group of localized, rebellious infections of the skin. Their administration is practically without danger, bringing about prompt cessation of the active infection and immunizing the patient against a recurrence of the infection for a more or less prolonged interval.

Clinical observations act as guides to the time for reinoculation and the size of dose to be administered.

The appropriate standards for size and frequency of doses have been previously established from opsonic estimations on laboratory patients with like infections, and are not necessary for each specific case.

Failure to immunize the patient artificially may be due to an abnormal condition of the skin, non-specific bacterial suspensions, or incorrect dosage.

Much time is saved in the use of stock suspensions by the elimination of opsonic indices and by the assistance derived from other therapeutic measures.

Less suffering, less deformity, less danger of systemic infection, and less liability to recurrence are the advantages derived from the use of bacterial suspensions as a therapeutic agent.

I am especially indebted, and wish to express my thanks to L. T. Clark, B.S., of the Research Laboratory of Parke, Davis & Co., for bacteriologic assistance and suggestions.

Washington Arcade.

ABSTRACT OF DISCUSSION

Dr. M. L. Heidingsfeld, Cincinnati: I have been more than favorably impressed with the results which I have secured from vaccine treatment in furunculosis, acne, sycosis and various forms of dermatologic affections complicated with secondary impetiginous infection. I have been induced to take up this form of treatment, largely by the favorable results which I have obtained in genitourinary work with gonococcus vaccine. I have had no experience with polyvalent stock vaccine, as my work has been entirely limited to monovalent vaccine as supplied by various wholesale drug houses and with autogenous preparations. I believe that the vaccine treatment will have a future field of great value and usefulness in a host of dermatologic affections of infectious nature.

Dr. John A. Fordyce, New York City: I would like to put on record two cases of infection of the skin in which the autogenous vaccines were used with good results. One was a case of vegetating dermatitis, with abscesses, in which the *Staphylococcus albus* was found. An autogenous vaccine was used for a number of months, and the patient improved remarkably, many of the abscesses disappearing. The patient gained eighteen pounds in weight, but finally reached the stage where improvement ceased. The second case was one of general infection with the *Staphylococcus aureus*. There were vegetations of the scalp and lower extremities, and from these lesions cultures of the organism were made. An autogenous vaccine was used, and the patient improved very much.

Dr. A. Ravogli, Cincinnati: I had a case of sycosis folliculitis, which proved extremely obstinate, and in which I resorted to injections of vaccines of the *Staphylococcus albus* and *S. aureus*. The injection was followed by a very marked reaction. The patient developed a temperature of 102.5 F., which lasted about twelve hours, perhaps longer. Following this, the eruption began to improve, the pustules almost drying up. Then there was a recurrence of the pustular lesions and a second injection was given. In spite of the fact that the dose was increased, the reaction was not so marked as in the first instance. Following this the pustules again partly dried up, and the patient left the hospital, but returned in a worse condition than before. Further injections were tried, but as they did not prove beneficial, they were stopped, and external remedies were substituted.

Dr. Alfred Potter, Brooklyn: We have had some experience with the vaccines in Dr. Winfield's service at the King's County Hospital in Brooklyn in the treatment of pustular and pemphigoid conditions. In one case of bullous eruption, of the hemorrhagic type in which we isolated a bacillus of the colon type, the patient was apparently going to die, but recovery took place under the vaccine treatment.

Dr. Henry H. Hazen, Washington, D.C.: In the dermatologic department of the Johns Hopkins Hospital we have used vaccine treatment in about twelve cases a week. In one case, that of a student with an eruption of the nose resembling pustular acne, we first tried the staphylococcus vaccine without effect, then a vaccine made from the acne bacillus also without effect. A culture was made, showing an unidentified bacillus, and under the use of a vaccine prepared from this rapid improvement resulted. I believe that one reason why we frequently have poor results from a stock vaccine is that the eruption is due to a different organism. I feel that if stock vaccines do not work we should make a culture from the lesion and prepare our vaccine from this.

Now, a word as to the use of Bier's hyperemia in conjunction with the vaccine treatment. The reason for using a vaccine is as follows: The lesion is so localized that the toxins from it do not enter the general circulation sufficiently to stimulate the body cells to the production of the necessary amount of antitoxin. Vaccine, however, enters the general circulation and causes the production of antitoxin. Now, if the necessary amount of toxin can not get to the body, it is also probable that the necessary amount of antitoxin can not get to the lesion, but a cup will bring much more serum to the part, hence more antitoxin.

Dr. H. R. Varney, Detroit: In testing the clinical value of this suspension, I confined its application to the treatment of furunculosis in order to determine, so far as possible, its efficiency. My experience with the use of the stock vaccine in acne has not been uniformly good. The infection is too often secondary to an abnormal condition of the skin, and while one may get temporary improvement, recurrences are most likely to take place. The most important question in connection with this discussion is: Can we simplify our technics so as to use a stock suspension? In the report which I made two years ago I stated that autogenous vaccines were more efficacious than the stock vaccine. In one of my cases (that of a physician who has long been a sufferer from boils) I had a special autogenous vaccine made. This was tried, with several recurrences, but the patient had not further recurrence after three inoculations of the *Staphylococcus aureus* suspension composed of 23 strains. I am strongly in favor of aiding the vaccine treatment by increasing the blood supply to the parts by the Bier hyperemic cupping method.

The age of the vaccine is a very difficult point to determine. The fact that one patient responds as readily to a vaccine that is six months old as another does to a freshly made vaccine does not throw much light on the value of the age of the vaccine, and *vice versa*.

Traveling Cooking Schools.—In Germany, to teach peasants how to cook cheaply and well, traveling cooking schools are sent about. When we secure a national health department this can be looked forward to in this country—as well as traveling schools of instruction on many other subjects related to the health of the people.

CHLOROFORM RATHER THAN ETHER ANESTHESIA IN TUBERCULOSIS *

JOSEPH WALSH, M.D.
PHILADELPHIA

Ether has been the anesthetic for so many years along the northeastern coast of the United States that it is almost heresy to even discuss it; yet experience seems to show that it is either very irritating to the lungs or stimulating to a tuberculous process in the lungs and hence should not be used when there is question of pulmonary tuberculosis. Surgeons generally admit that ether is irritating to the lungs and yet they not only continue to administer it in cases of pulmonary tuberculosis, but also very rarely discuss the matter.

Wood's "Text-Book on Therapeutics" (thirteenth ed., 1906) recommends with Hewitt that in extreme emphysema, in chronic bronchitis attended by expectoration and dyspnea and in advanced pulmonary phthisis, chloroform or some other mixture containing chloroform should be employed. He adds that acute pulmonary disease especially contraindicates ether.

During the past six years I have never allowed my own patients with pulmonary tuberculosis to be operated on under ether when it was possible for me to prevent it. Moreover, all except one have been operated on under chloroform, and I have never seen any bad results that could possibly be attributed to this anesthetic.

During the same period I have seen a number of patients manifesting active tuberculosis of the lungs following operation, which activity appeared from a study of the history to be due either to the operation itself or to the ether anesthesia. The common operations in these cases were for enlarged glands of the neck, fistulas, appendicitis, enlarged tonsils and adenoids.

The following represent several cases taken from my records without selection which I had opportunity to examine and watch for some time before and after an operation with anesthesia:

ETHER ANESTHESIA

CASE 1.—*History.*—A woman, aged 27, had four attacks of appendicitis before I saw her Sept. 12, 1906. Her brother had at the time advanced tuberculosis of the lungs. She showed a very small lesion slightly active at the right apex and some wasting, weighing only 109 pounds when her normal weight was 129. In the next three months she improved to practically perfect well-being and on Dec. 11, 1906, was operated on for appendicitis under ether anesthesia. I have never been able since to get her in as good condition as she was before the operation, and in the meantime the lesion at the right apex has increased so that it is now definitely down to the second rib.

CASE 2.—*History.*—A case of Dr. Stanton's which I also saw several times and which is quite typical is as follows: A woman, aged 25, was perfectly well till she developed ischiorectal abscess. The ischiorectal abscess was operated on one year ago under local anesthesia and later a radical operation was done under ether. Within three days the temperature had risen to 103 F., she began to spit blood, and since, tuberculosis of the lungs, which was then first noticed, has greatly advanced. She is now in a practically hopeless condition.

CHLOROFORM ANESTHESIA

CASE 1.—*History.*—A woman, aged 21, was first seen Nov. 4, 1902. She had an infiltration of the upper half of the upper lobe on each side and coarse moist râles all over both lungs. She expectorated profusely and her sputum contained an innumerable number of tubercle bacilli for a year and a half after I first saw her. While those signs remained practically the same, but after she had definitely increased in weight and was in pretty good constitutional condition she developed, Sept. 7, 1903, an abscess of the breast (probably tuberculous), which was opened and radically cleaned out under chloroform anesthesia without the slightest bad symptom following. The patient came to my office ten days later and continued her treatment, and for the past two years she has been entirely well, without active physical signs in the chest, and without any cough or expectoration. On account of the intense irritation already manifested in both lungs I should have expected this patient to do very badly under ether.

CASE 2.—*History.*—A woman, aged 29, was first seen on Jan. 24, 1905. On May 23, 1905, she developed tuberculosis, apparently having contracted it from her husband, who was in an advanced stage. Her lesion was at the right apex and was definitely apparent and active. She became entirely well, and in January, 1908, developed appendicitis. She was operated on under chloroform, was out of the hospital in fourteen days, and since then has manifested no pulmonary irritation. In this case the lung condition was apparently cured or at least quiescent when she underwent the operation.

CASE 3.—*History.*—A woman, aged 25, was first seen Feb. 16, 1903. She had infiltration of the top of both lungs extending to the second rib with some dissemination. She went to the White Haven Sanatorium, became entirely well and was a nurse there for two years, when she developed pneumonia. It took a year to get over the pneumonia and its toxic effects. Three months later she developed acute appendicitis, for which she was operated on under chlorotorm anesthesia. She was out of the hospital in two weeks and has never had any symptoms since.

CASE 4.—*History.*—A woman, aged 24, was first seen Aug. 18, 1904. She had markedly enlarged right cervical glands, cavity at the top of the right lung and infiltration of the upper half of the left upper lobe. Was operated on for the enlarged cervical glands shortly after I first saw her under chloroform anesthesia. She became sufficiently well to enter the Phipps Hospital Training School, where she remained for a year, when she broke down from overwork and eventually died. The chloroform anesthesia, however, appeared to have rather a good than a bad effect.

NITROUS OXID GAS ANESTHESIA

CASE 1.—*History.*—A man, aged 18, was first seen in March, 1908, at the White Haven Sanatorium. History showed that pulmonary symptoms first developed in April 1907. The physical signs were those of tuberculous infiltration of the upper half of the right upper lobe. About three weeks after admission to the sanatorium he developed a large ischiorectal abscess which was opened. A radical operation was performed under nitrous oxid gas on Aug. 1, 1908. The abscess was very large, making the operation correspondingly serious. He continued to improve exactly as before the operation, never showed the slightest activity after the operation and left the White Haven Sanatorium with the "disease arrested" at the end of September, 1908, and since then has remained in perfect condition.

The mere statement of the cases makes it appear that chloroform might even be somewhat curative, and this has been asserted by some, especially Holmes and Woodcock of London. I am not ready, however, to advocate chloroform in the cure, but do believe that in case of necessary operation with anesthesia, chloroform should be the anesthetic and not ether. Moreover, chloroform should be administered, not only in all cases of tuberculosis of the lungs, but in all cases in which tuberculosis of the lungs may be suspected, like, for instance, cases that manifest tuberculosis elsewhere, as in the cervical glands, in the ischiorectal region, etc.

732 Pine Street.

Peritonitis Patients.—E. C. Rich, in *Denver Medical Times and Utah Medical Journal*, says that it is a well-established fact that patients with peritonitis stand short operations well, but long ones very badly.

ANATOMY AND PHYSIOLOGY OF THE TONSIL*

CHARLES M. ROBERTSON, A.M., M.D.
Professor of Rhino-Laryngology, Chicago Policlinic
CHICAGO

The tonsils are two masses of lymphoid tissue placed one in each tonsillar fossa and projecting into the oropharynx. They are oblong in shape with the long axis vertical. They are from 1.75 to 2.5 cm. in length and from 1.5 to 2 cm. in transverse diameter. In children under the age of eight they are usually larger, from 2.5 to 3 cm. in long axis by 1.5 to 2.5 in transverse diameter. They are covered by stratified epithelium of the mucous membrane and their pharyngeal surface is marked by small apertures which indicate the openings of the crypts. The epithelial lining of the crypts is reflected from the surface covering.

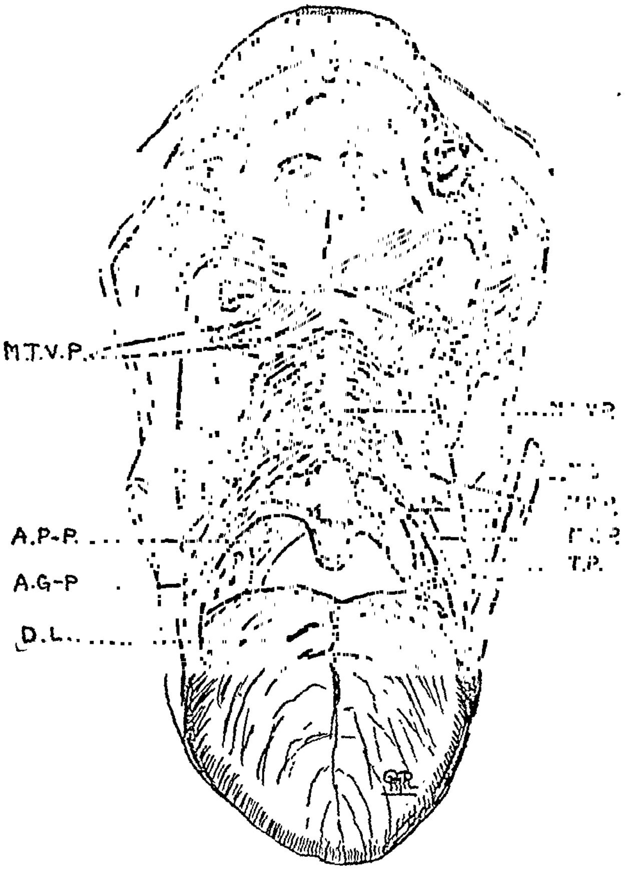

Fig. 1.—Showing anterior pillar (after Toldt): M. L. V. P., M. levator veli palatini; M. S., M. styloglossus; M. P.-P., M. pharyngopalatinus; M. G.-P., M. glossopalatinus; T. P., tonsilla palatina; M. T. V. P., M. tensor veli palatini; A. P.-P., arcus pharyngo-palatinus; A. G.-P., arcus glossopalatinus; D. P., dorsum linguæ.

The tonsils are composed almost entirely of lymphoid tissue which at intervals is aggregated into lymph nodes in which the lymph cells are more intimately arranged than elsewhere. The lymphoid tissue is surrounded by a dense capsule of connective tissue and the gland is divided into pockets by the trabeculæ, which are composed of connective tissue. The tonsil is part of the lymphatic circle which surrounds the oropharynx, called Waldeyer's ring.

In the neighboring part of the pharynx near the Eustachian tube, the upper part of the pharynx and the base of the tongue, there are masses of lymphoid tissue similar in structure to that of the tonsil, which also contain crypts.

FORMATION OF THE TONSIL

The tonsil makes its appearance about the fourth or fifth month of gestation. At birth it is a gland from 0.5 to 1 cm. in its long axis and from 0.25 to 0.5 cm. in lateral dimension. It develops as the child grows, reaching its full size between the sixth and eighth year of life. After this period it begins to atrophy and has disappeared by the twelfth year. At birth it is enclosed in the tonsillar fossa, being completely covered by the plica tonsillaris. Shortly after birth this membrane disappears, leaving the inner surface of the gland exposed to the oropharynx.

It is small at birth as compared with the thymus or thyroid gland. It is formed in the fetus by an invagination of the hypoblast which forms the capsule and the trabecular pouches or areas. The epiblast extends down into these trabecular areas and forms the crypts around which lympathic tissue develops.

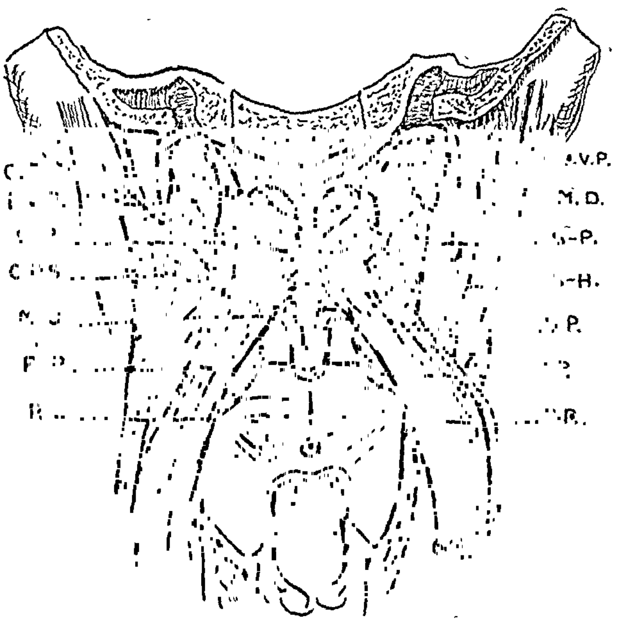

Fig. 2.—Showing posterior pillars (after Toldt): C. T., cartilago tubæ; M. L. V. P., M. levator veli palatini; M. S.-P., M. salpingopharyngeus; M. C. P. S., M. constrictor pharyngis superior; M. U., M. uvulæ; M. P.-P., M. pharyngopalatinus; R. L., radix linguæ; M. T. V. P., M. tensor veli palatina; M. D., M. digastricus; M. S.-P., M. stylopharyngeus; M. S.-H., M. stylohyoideus; U. P., uvula palatina; T. P., tonsilla palatina; M. P.-P., M. pharyngopalatinus.

ANATOMIC DESCRIPTION

The tonsil is situated between the anterior or glossopalatine fold and the posterior or palatopharyngeal fold. It is covered externally by the superior constrictor muscle. It does not completely fill the tonsillar fossa, there being a space above which is known as the supratonsillar space, or fossa, and it is sometimes found in unusual positions.

One case is reported in which the gland occupied a position on the posterior pillar just under the Eustachian tube. In two other cases the tonsil was attached to the posterior pharyngeal wall behind the uvula. In these cases the gland was pedunculated but contained well-defined crypts.

---

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

Palatal Pillars.—The anterior pillar is formed by the palatoglossus muscle, which is attached above to the aponeurosis of the velum and has its insertion in the tongue. Its action is to constrict the isthmus of the fauces and holds the tonsil back in place. The free edge is often attached to the tonsil by inflammatory adhesions from repeated attacks of tonsillitis. It may vary considerably in thickness and appear as a rough red membrane, with the outline indistinct or irregular. In other types it may appear so thin as to be almost transparent. At times the anterior pillar is found attached to the posterior pillar by a thin membrane which may be complete or partial, which is the remains of the plica tonsillaris (Fig. 1).

The Posterior Pillar.—This tissue is formed by the mucous membrane fold in which is contained the palatopharyngeus muscle. This muscle arises in the soft palate with fibers from its fellow of the opposite side. It passes partly above and partly below the levator palati and azygos uvulæ muscles. After forming the posterior pillar of the fauces the internal fibers are inserted into the pharyngeal aponeurosis and the external fibers pass forward to be inserted into the posterior border of the thyroid cartilage. The action of this muscle is to contract the isthmus of the fauces and to lift the soft palate. During inspiration the two pillars meet or nearly meet in the median line, thus shutting off the oral cavity from the respiratory tract (Fig. 2).

Plica Tonsillaris.—Some authors divide this membrane into two parts, the plica supratonsillaris and the plica triangularis. In truth the plica supratonsillaris is only a remaining part of the plica tonsillaris. The term plica triangularis should be discontinued because this membrane is not triangular in shape. Plica tonsillaris gives a better understanding of the correct significance of the membrane, which at birth is a normal embryonic tissue but which should completely disappear before the second year. If present after this age it is an abnormal remnant. When the plica tonsillaris does persist it is a continuation of the edge of the anterior pillar and may join the two pillars above, forming a band or fold over the upper part of the tonsil. The most common manifestations, however, are those tonsils which have the anterior edge covered by this membrane to a greater or less extent. It is impossible in many cases to define the edge of the anterior pillar.

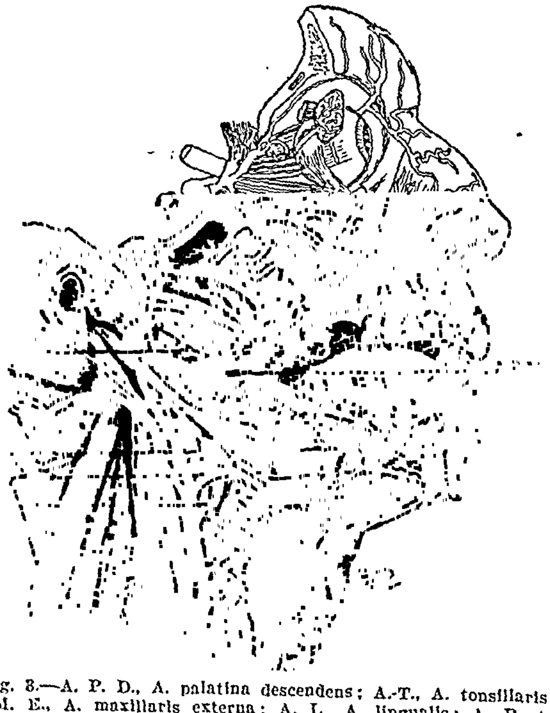

Fig. 3.—A. P. D., A. palatina descendens; A.-T., A. tonsillaris; A. M. E., A. maxillaris externa; A. L., A. lingualis; A. P. A., A. palatina ascendens. (Modified after Toldt.)

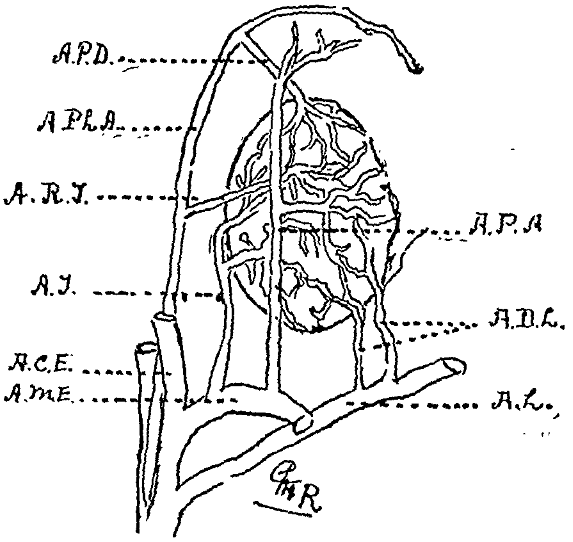

Fig. 4.—Schematic circulation circle of tonsil: A. P. D., A. palatina descendens; A. Ph. A., A. pharyngea ascendens; A. R. T., A. ramus tonsillaris; A T., A tonsillaris; A. C. E., A. carotis externa; A. M. E., A. maxillaris externa; A. L., A. lingualis; A. D. L., A. dorsalis linguæ; A P. A., A. palatina ascendens.

In 1906 I read before this Section a paper describing the common types of this membrane, mentioning, among others, a case in which the membrane completely covered the tonsil in an adult.[1]

Supratonsillar Fossa or Recessus Palatinus.—The supratonsillar fossa is a triangular, conical space with the apex outward, and when normal represents a considerable cavity above the tonsil. Its walls are formed by the anterior and posterior pillars, while the floor is formed by the superior surface of the faucial tonsil. It varies in size in different individuals and may differ from the fossa of the opposite side. It may extend downward and outward, external to the tonsil, or up and outward into the soft palate. There may be sinuses extending off from this space in one or more directions. This fossa is of importance from the fact that there are crypts emptying into this space and when the communication with the pharynx is imperfect or absent a collection of caseous material may be extruded from the tonsil, held in this space. This condition is the great cause of the infections which pass through the gland into the cervical lymphatics, and also the cause of the different types of quinsy from decomposition of this extruded material held in the supratonsillar space.

CAPSULE OF THE TONSIL

The tonsil has a capsule extending from the free edge of the pillars covering the external surface of the gland which furnishes support as well as an investing covering. This capsule is composed of connective tissue about 1 mm. in thickness and is smooth on the external surface. From this capsule bands of connective tissue called the trabeculæ are given off, which extend to the inner surface of the gland dividing it into spaces called the trabecular areas. In these trabecular bands lie the vessels, nerves, mucous ducts and lymph channels.

---

[1] Faucial Tonsils, The Journal A. M. A., 1906, xlvii, 1725.

In some of the lower animals we find muscular tissue in these bands, but not in human beings.

Trabecular areas are supposed to be separate and distinct spaces, although Beck has injected bismuth paste into one crypt and has seen it communicate with four or five other trabecular spaces.

The youngest patient was eight years of age, while all the others were adults. This communication between crypts is at variance with my experience and I am inclined to the belief that the phenomenon observed by Beck is pathologic.

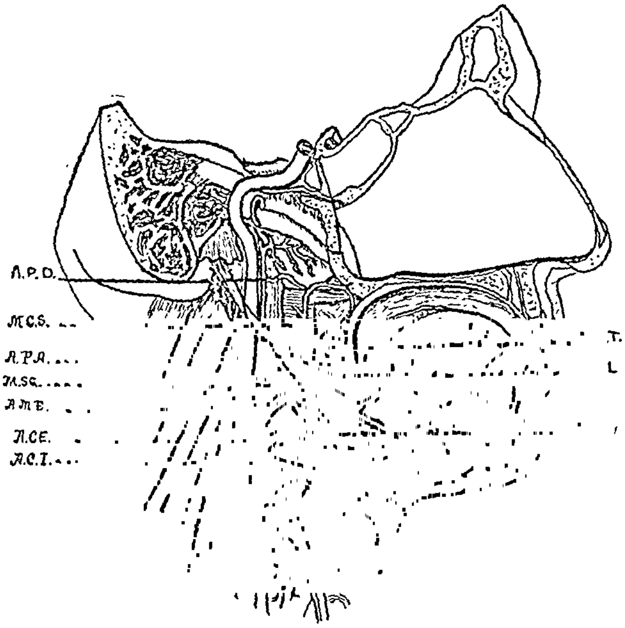

Fig. 5.—A. P. D., A. palatina descendens; M. C. S., M. constrictor superior; A. P. A., A. palatina ascendens; M. S. G., M. styloglossus; A. M. E., A. maxillaris externa; A. C. E., A. carotis externa; A. C. I., A. carotis interna; A. R. T., A. ramus tonsillaris; A. D. L., A. dorsalis linguæ; A. L., A. lingualis. (After Toldt.)

CRYPTS

The crypts vary in number and length. Some authors place the number at from fifteen to eighteen. I have seen many tonsils which had as few as four or eight. The number depends upon the size and condition of the tonsil examined. In the upper half of the tonsil the crypts are longer, usually extending downward and outward to the capsule on the external surface of the gland. Those opening below the middle of the gland extend outward or outward and upward. They are much shorter than the upper crypts. The upper crypts, especially those which empty into the supratonsillar fossa, are usually filled or partially filled with caseous material, while those emptying directly into the pharynx are seldom found with material in the crypt. This fact is easily explained by remembering that when swallowing the tonsils are squeezed by the palatal and superior constrictor muscles. This empties the crypt of material if there be no obstruction at its mouth, in which case the material cannot escape from the pressure of the obstruction.

If there be a tonsil which fills the supratonsillar fossa or a plica tonsillaris covering over the crypt walling the supratonsillar fossa off from the pharynx the material in the crypt can not be expelled, or if expelled is held in the supratonsillar fossa, and in this case it follows the line of least resistance, which usually is deeper into the crypt. Thus there may be a crypt, or number of crypts, enlarged at the distal end, or branching sinuses may be produced. This would perhaps account for the bismuth paste finding its way into three or four different crypts, as seen by Beck.

The crypt is lined by stratified epithelium. This membrane is much thinner than the surface membrane, and some observers assert that it disappears in the extreme depth of the crypt. At places in pathologic glands this crypt lining is very thin, from the presence of great numbers of lymphocytes, which seem to separate the lining membrane cells. The subepithelial tissue is also lost in the crypt, the lymphoid cells coming in direct contact to the crypt wall.

BLOOD VESSELS OF THE TONSILS

The blood supply of the tonsil is derived from (a) the tonsillar artery, which is a branch of the external maxillary near its origin from the external carotid; (b) from the ascending pharyngeal, which is given off from the external carotid just above the bifurcation of the common carotid; (c) from the ascending palatine, a branch of the external maxillary; (d) from the dorsalis linguæ by one or two branches from the lingual.

These arteries supply the tonsil and tonsillar space as follows:

(*a*). The tonsillar artery is given off from the external maxillary, a branch of the external carotid (Figs. 3 and 4). It passes upward and forward under the jaw and the internal pterygoid muscle and under the styloglossus into the loose fatty tissue of the pharyngomaxillary space. At or below the middle of the tonsil the artery gives off a branch which passes to the buccopharyngeal fascia which covers the superior constrictor muscle externally. Here the artery divides into a superior and an inferior branch. These two branches pass through the superior constrictor muscle and divide on the capsule of the tonsil into numerous ramifying branches, which enter the tonsil along the trabecular bands. In hypertrophied tonsils this artery is sometimes large and may cause troublesome hemorrhage.

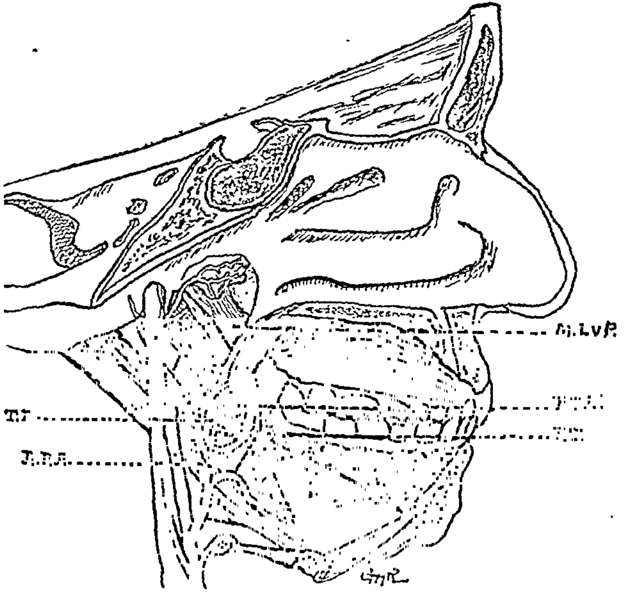

Fig. 6.—T. P., tonsilla palatina; A. P. A., A. palatina ascendens; P. T. A., pillaris tonsilla anterior; R. T., ramus tonsillaris; M. L. V. P., M. levator veli palatini. (After Toldt.)

(*b*). The ascending pharyngeal is a small branch of the external carotid. It is a long, slender vessel, deeply seated in the neck beneath the other branches of the external carotid and the styloglossus muscle. It arises from the back part of the external carotid near the origin of the vessel and passes up to the under surface of the base of the skull, ascending the neck between the internal carotid and the side of the pharynx, lying on the rectus capitis anticus major muscle. It gives off a tonsillar branch opposite the tonsil which passes forward on the superior constrictor muscle, which it pierces and then divides into ramifying branches on the tonsil.

It also sends branches to the Eustachian tube and soft palate. Above the edge of the superior constrictor muscle it gives off the descending palatine which passes under the constrictor muscle and anastomoses with the ramifying branches of the tonsillar or ascending palatine artery (Figs. 3, 4, 5).

(*c*). The ascending palatine, a branch of the external maxillary, passes up between the styloglossus and stylopharyngeus to the outer side of the pharynx, after supplying these muscles, the tonsil and the Eustachian tube (Figs. 5, 6). It divides near the levator palati into two branches; one follows the course of the tensor palati, supplying the soft palate and palatine glands, the other passing to the tonsils, which it supplies, the branches anastomosing with the tonsillar artery when present and descending palatine branch of the ascending pharyngeal.

(*d*). The dorsalis linguæ arises from the lingual artery at the anterior margin of the hyoglossus muscle, ascending to the dorsum of the tongue. It supplies the mucous membrane of the tonsil, the palatine pillars and the epiglottis, anastomosing with its fellow from the other side and the ascending palatine or tonsillar artery (Figs. 4, 7, 8).

ANATOMIC RELATIONSHIPS

The tonsil is in relation in front, with the anterior pillar; internally, with the oropharynx; above, with the supratonsillar space; externally, with connective tissue external to which lies the superior constrictor muscle of the pharynx. "The pharyngomaxillary space lies external and behind the tonsil. The "pterygopharyngeal space[2] is an irregular conical space, more or less triangular in cross section (Fig. 9). It contains a varying amount of fatty areolar tissue, in which lie the ascending palatine and tonsillar arteries. It is bounded externally, by the internal pterygoid muscle; internally, by the wall of the pharynx; posteriorly, it communicates with the fatty tissue of the pharyngomaxillary space which lies adjacent to the posterolateral wall of the pharynx. In the pharyngomaxillary space lie the internal and external carotid arteries, the internal jugular vein with its branches, the vagus and hypoglossus nerves and the styloid muscles. The tonsil rests on the medial side, and is therefore separated by the fascia and fat of the space from the pterygoid muscle and mandible against which it is pressed."

The internal carotid lies backward from the tonsil at a distance of 1.5 cm. and the external carotid backward and outward at a distance of 2 cm. They are therefore separated from the tonsil by the superior constrictor and the stylopharyngeus and to some extent the styloglossus muscle (Figs. 1, 2, 9).

The Eustachian Tube.—The Eustachian tube lies just above and a little behind the tonsil at a distance of 1 to 1.5 cm. and in cases of hypertrophy of the gland upward and outward it often extends along the course of the tube, causing tubal occlusion or inflammatory reaction by continuity of tissue (Fig. 2). This is a frequent cause of tinnitis aurium.

CERVICAL LYMPHATICS

The tonsil has for its afferent lymphatics the deep branches from the nose and some branches from the tongue. The efferent branches empty into both superficial and deep cervical chains through the peritonsillar glands which lie external to the internal jugular and in close relation to it. (This chain encircles the jugular.) These glands can be demonstrated in children as the glands commonly removed by surgeons for tuberculosis. The lymph from this chain of glands is emptied into the jugular trunk, which, with the lymph from the subclavian trunk, is emptied directly or by means of the thoracic duct into the vena cava. There are numerous anastomotic branches between these glands, and the flow of lymph is not always in one direction. It may flow in any direction, seeking the line of least resistance through these anastomotic branches. This accounts for infection being carried differently at different times. If the current were constant in its direction infection would travel in one direction only.

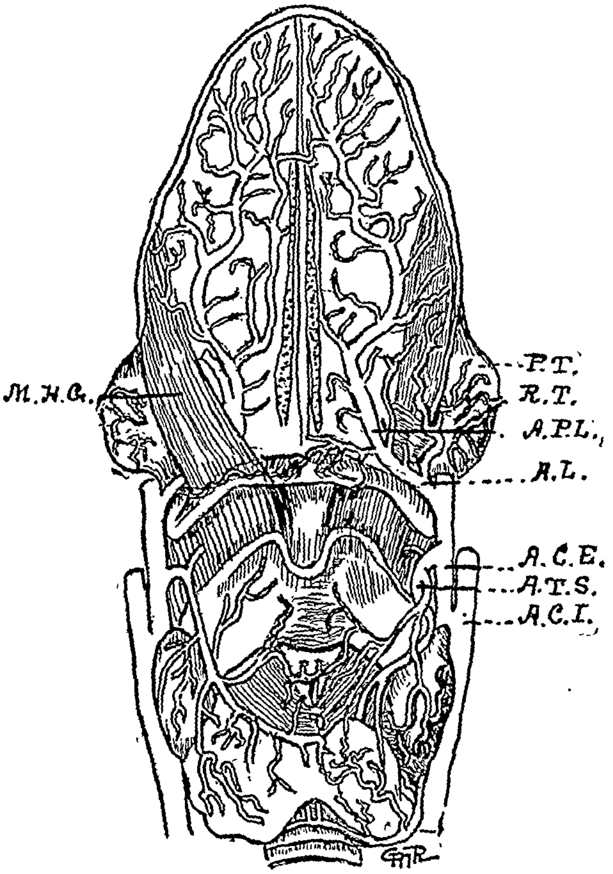

Fig. 7.—M. H. G., M. hyoglossus; P. T., tonsilla palatina; R. T., ramus tonsillaris from A. palatina ascendens; A. P. L., A. profunda linguæ; A. L., A. lingualis; A. C. E., A. carotis externa; A. T. S., A. thyroidea superior; A. C. I., A. carotis interna. (After Toldt.)

PHYSIOLOGY OF THE TONSIL

The true function of the tonsil has to do with early life and at birth the gland is so small as to be unimportant. It attains its full development by the sixth or eighth year and then begins to atrophy. By the age of twelve or fourteen it has completely disappeared or shows as a hypertrophied or a cicatricial mass between the palatine pillars. Any tonsil which is visible to any marked degree later than this may be considered as a morbid growth due to disease.

[2] Wilson: Anatomy and Physiology of the Tonsil, The Journal A. M. A., May 26, 1906, xlvi, 1593.

It has been stated by some writers that children with adenoids and enlarged faucial tonsils are backward mentally. In a report of examinations of school children those of certain ages were compared both as to the presence of lymphatic growths and the grade obtained in school. It was determined that at the age of six 40 per cent. of children had adenoids and tonsils; those at the age of eight, 32 per cent.; those at the age of ten, 20 per cent., and those who had reached the age of twelve had 15 per cent. Therefore, if children of six years of age be compared with those of eight, we will find 8 per cent. more having adenoids and tonsils than those at eight years. Children at eight years will have 12 per cent. more than those at ten, while those at ten will have 5 per cent. more than those at twelve years. The backward student will have a less percentage than his associate in school who is younger and brighter in his school work. This statement must be modified, however, because students of eight years will be few in number and of these few probably all will show the presence of adenoids and tonsils, which might prove the child with these growths was really backward.

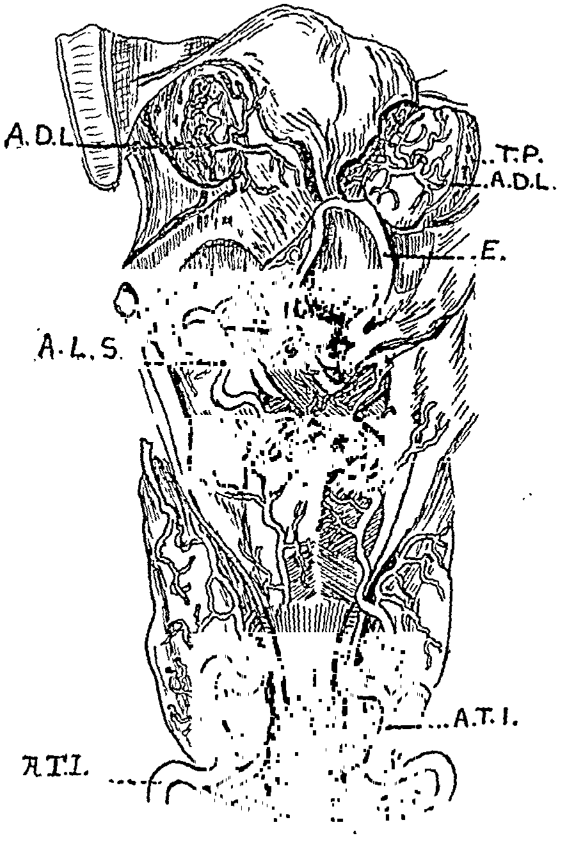

Fig 8.—A. D. L., A. dorsalis linguæ; A. L. S., A. laryngea superioris; E., epiglottis; T. P., tonsilla palatina; A. T. I., A. thyroidea inferioris. (After Toldt.)

Clinically, nearly all children at six have adenoids and tonsils; at eight, probably 85 per cent.; ten, 35 per cent., and at twelve, about 15 per cent.

It has always been understood that the tonsil was responsible for most of the diseases of childhood and many of the circulatory, respiratory, as well as nervous diseases.

It is probable when the child has a pathologic condition of this structure that all kinds of infections may occur. The tonsil can be infected by cultures applied on the investing membrane and more easily by introduction of bacteria into the crypts where the mucous lining is less of a barrier on account of its thinness. Various infections may be traced to the tonsil as a portal of entry, but this phase of the subject is not in the scope of this paper. Some authors claim the tonsil as a part of the digestive tract, basing their view on the idea that in respiration, unless the gland is pathologically hypertrophied, the tonsil is cut off from the ingoing current of air; because when the mouth is closed in the act of respiration the tongue is pressed back and the posterior pillars contract so that they nearly, if not quite, meet in the middle line. This presses the faucial tonsil against the base of the tongue and covers it by the posterior pillars, so that the ingoing current of air does come in contact with it.

It is said that the lymphocytes pass into the stomach, having escaped from the tonsillar crypt, and in the stomach become the salivary follicles aiding in digestion. It is also said that particles of food are forced into the tonsillar crypt during deglutition and here act as irritants, being partially at least digested in this place, or produce, as a result of their influence on the tonsil, the production of antibodies or antitoxins.

In contradiction to this theory it is found that if pieces of healthy tonsils are ground with water and the solution filtered the fluid produced will have no effect on albumin or beef broth, showing the absence of enzymes in the product of the tonsil, and therefore that the digestive function is *nil*. The same fluid placed in a test tube with typhoid or the commoner forms of germs all have a like turbidity, showing the bactericidal property wanting.

One author has the idea that the endothelium in the crypt undergoes a transformation into lymphocytes which enter the tonsil from without inward, but this has never been proved to the satisfaction of others.

We are told by Stöhr that the true physiologic function of the tonsil lies in the lymphoid nodules. In these nodules the center, which is termed the germ center, breaks down, changing the lymphoid tissue into lymphocytes. These lymphocytes are migratory cells and escape into the crypt in quantity through the mucous membrane lining, and thus find their way to the surface of the gland, carrying with them digested bacteria and effete material—phagocytosis.

It is known that the presence of lymphocytes exercises no influence on bacteria unless aided by some more developed leucocyte. If there is inflammation or infection in a gland it is the function of the eosinophiles to pour out opsonins, after which the lymphocytes will march up in quantity, surround, digest and carry off the residue. It is probable that the eosinophile is a product of some organ other than the tonsil, so the tonsil can not be considered an organ of destruction for bacteria, as it cannot do this without the assistance of some other tissue, probably the spleen or bone marrow in which the eosinophile is formed, which seems essential to the phagocytotic function..

So far as I can learn, the physiology of the tonsil, as we know it, has been limited to the study for the most part of pathologic glands, and has not included the so-called normal tonsil, which marks its decline after the sixth or eighth year.

If the tonsil in a normal state is removed *in toto* there is no disastrous after effect, as in the case of the thyroid. On the other hand, the individual is improved in health; in the young this is simply from the fact that respiration is carried on in a proper way by not being impeded by a mass which acts as an obstruction.

After the age of six or eight years, when the function of the tonsil begins to disappear, the general condition of health is invariably improved by the removal of the gland. It is a common occurrence for these patients to gain one or two pounds a week after removal of the glands. This is produced in one of two ways; first, by the removal of an obstructing mass to respiration; second, by removal of an infecting focus.

It is probable that the lymphatics of the nose, nasopharynx and oropharynx, have some function with the formation of the face and the accessory cavities of the nose, and therefore it appears to me that their function is an ancestral or developmental one. This is reasoned from the fact that they are present *ad maximum* during the time when such changes are taking place. Thus at birth the superior maxilla is only partly formed. The orbit is well formed, as is the mouth, but the mouth lies almost in direct contact with the lower border of the orbit, the rudimentary teeth being the only tissue separating the two cavities. The body of the sphenoid bone is not developed, the sphenoidal sinus being a small cavity not more than 2 or 3 mm. in diameter; the ethmoidal cells are mere depressions in the middle turbinal; the frontal sinus can not be seen, as the two frontal plates have as yet not separated, and the antrum of Highmore is only a small slit 3 or 4 mm. in length, situated between the nasal cavity and the infraorbital foramen, just inward and below the orbit, while the nasal bones are simply small projections in the beginning of formation.

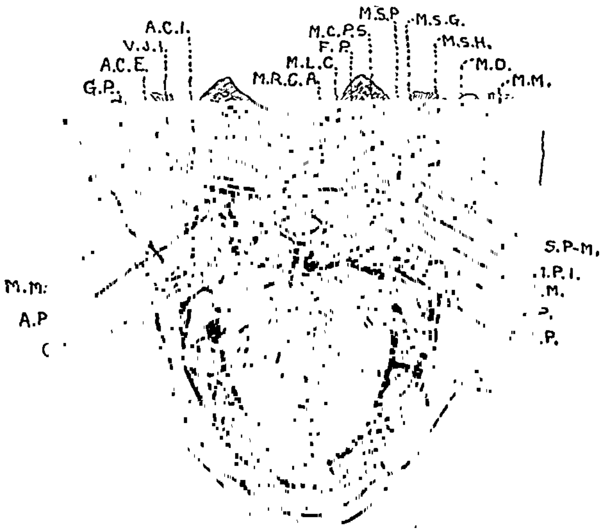

Fig. 9.—Showing relation of parts after Toldt): A. C. I.. A. carotis interna; V. J. I., vena jugularis interna; A. C. E., A. carotis externa; G. P., glandula parotis; M. R. C. A., M. rectus capitis anterior; M. L. C., M. longus capitis; F. P., fascia prævertebralis; M. C. P. S., M. constrictor pharyngis superior; M. S. P., M. stylopharyngeus; M. S. G., M. styloglossus; M. S. H., M. stylohyoideus: M. D., M. digastricus; M. M., M. masseter; S. P. M., spatium pharyngomaxillaris; M. P. I., M. pterygoideus interna; R. M., ramus mandibulæ; T. P., tonsilla palatina; A. G. P., arcus glossopalatinus; A. P. P., arcus pharyngopalatinus.

It seems to me that the lymphatics of the nose, nasopharynx and oropharynx were occupied with the process of katabolism after the blood had at least in part finished the process of anabolism. In this manner the broken-down tissue finds its way into the deeper lymphatics of the nose and from thence through the postpharyngeal, tonsillar and submaxilliary glands into the general lymphatic current. It may also be possible that the tonsils are stimulated by this process into producing some substance which is given to the blood, which in turn regulates some function which is active at this period of tissue formation and absorption.

It is evident that if we are to ascribe any function to the glands it must be one which is active during the first part of the child's life or between the first and sixth or eighth year, at which period the gland has already passed its height of usefulness in the economy and is beginning to disappear by atrophy.

It is claimed that the tonsil, in particular cases, has come to have a function in modulating the voice. This, however, I look on as a mere matter of education, and the singer or speaker would have come to modulate the voice just as well without this gland as with it. On the other hand, we have all seen cases in which voice was increased in tone and volume by the removal of these growths. The richness of quality and volume of tone is often added to 100 per cent. after the enucleation, provided the pillars remain intact and are not bound down or together by cicatricial tissue. I have observed four patients in whom there was loss of voice who were relieved by removal of the tonsils. These individuals are usually affected in one register, more frequently the middle.

The removal of tonsils in the adult can not be studied in this connection, however, as the presence of such growths is a pathologic phenomena.

I still believe that tonsils after the sixth or eighth year of life are pathologic in their character and as such are productive only of detrimental influence in rendering the individual unable to cope with infections of various kinds, and thereby working a hardship to the general economy.

It is true that I am making a rather sweeping statement as regards the function of this gland and one which may bring much criticism by the members of the profession, but it seems to me the investigations so far as published by the various writers are of little value, having been observed from an erroneous viewpoint.

CONDITIONS OF THE FAUCIAL TONSIL WHICH CALL FOR OPERATIVE INTERFERENCE*

EMIL MAYER, M.D.
Adjunct Attending Laryngologist and Chief of Clinic, Throat and Ear (Out-Patient) Department, Mount Sinai Hospital
NEW YORK

The conditions of the faucial tonsil which call for operative interference may be divided into two classes: (1) Simple hypertrophy causing interference with respiration; (2) diseased conditions of the tonsils themselves causing local or constitutional infection.

SIMPLE HYPERTROPHY

While tonsils have been removed from time immemorial—it was certainly done by the ancients—it is only of late years that much study has been given to the evils of mouth breathing and attention drawn to the improvement in the health and morale of children after proper breathing has been restored.

---

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

It is by no means unusual to see children who are irritable and often possessed of vicious traits become gentle and kind, dullards to show a new vivacity and the slovenly youth to awaken to a sense of order and decency. Witnessing these results, we often hesitate to mention the lasting effects and often marvelous changes subsequent to tonsillar operation, lest we be considered too enthusiastic.

This subject, however, has been taken up by educators and public health officials and has their hearty approval. One of the earliest to note the improved morale of children whose tonsils had been successfully removed was Dr. John J. Cronin, at that time chief of the department of child hygiene of the Health Department of New York City.

In the efforts to stamp out trachoma all defects among school children were noted, and a large number of children were found with hypertrophied tonsils, usually associated with an adenoid growth. These children were advised, by postal cards sent to the parents, to see their physicians, and so it came about that a large number of school children appeared in the various dispensaries of the city. At first the school nurse or inspector of the department accompanied them, but afterward the parents brought the children, and a large number were operated on. Among them were one class of children from a school where those who were continuously deficient were sent, so that it was known as the school for defectives. The principal of this school noticed, to her surprise, that some of these children improved wonderfully in their studies, as well as in deportment, and she became an enthusiastic advocate of an operation that would help these especially unfortunate children to become useful members of the community. Some of the children showed an improvement of 100 per cent. over their former ability to work and in behavior.

A brief report from Cronin's[1] description as to what happened subsequently may be of interest:

> There was a special class of defective children, composed of backward and incorrigible children, truants and so-called impossibles examined by an inspector who devoted his entire time to diseases of children. Of 150 children, 13 had defective vision and the remainder had an adenoid or enlarged tonsil or both. Special effort was made during six months to have these children operated on. Parents were neglectful (often too poor to lose the time to go to the hospital for operation, frequently not having car fare to travel the distance), and only 56 of these were attended to.
>
> It was thought justifiable to get what scholastic results would be obtained if these children were operated on collectively. Written consent was readily obtained from the parents to perform the necessary operations, and on June 21, 1906, 81 children were operated on in the afternoon by my two assistants, Dr. Yankauer and Dr. Ballin and myself.
>
> Six months later 76 of these children were re-examined and without exception they had all been promoted and were doing well in advanced grades.

To meet the exigencies of the examination by the medical inspectors of schools certain rules have been formulated for their guidance. It must be remembered that no previous history is obtainable, and also that no further examination than depressing the tongue with a wooden spatula (which is immediately thrown away) is permissible. Hence, only such tonsils as interfere with proper respiration, thus retarding development, are considered in the recommendation for removal. Full notes of the condition found are made, a notice of the recommendation of the inspector is mailed to the parents or guardians of the child and evidence is subsequently required that a physician has been consulted. When there is neglect the school nurse often interviews the parents and tries to convince them of the need of the child. Occasional complaints have arisen that children were refused instruction unless they were operated on, but investigations show these to be apparently unfounded. This public work of such vast importance has now been taken up throughout the civilized world and none of us will gainsay its appropriateness and lasting value.

DISEASED CONDITIONS OF TONSILS CAUSING INFECTION

Passing to the second classification I shall deal first with such affections of the tonsil itself that indicate the need for extirpation and secondly with constitutional disturbances associated with and dependent on a diseased state of the tonsil. The most common of all these in the first category is acute lacunar or follicular tonsillitis, with its onset of high fever and general disturbance, sore throat and deposit on the tonsillar surface, the latter often making a clinical differentiation between it and diphtheria impossible without a bacteriologic examination.

It is most common in children, and recurrences of the attack are the rule. In some children the recurrences are so frequent as to make them lose much time from their school work for many months of the year.

I recall the history of two brothers in my practice who had had so many attacks of tonsillitis of this variety that they were rarely free from attacks for two consecutive months. A physician previously consulted invariably injected antitoxin as a precaution, and they dreaded his approach. Extirpation of both tonsils with adenoids has cured the boys completely.

Peritonsillar abscess is practically a disease of adult life, although, through the courtesy of Dr. Sara Welt, I have recently seen this affection, in which streptococci were found, in a child of ten months. Cornet[2] reports a case of this affection in a child aged nine months. Here also recurrence is the rule, unless the tonsil is effectively removed.

Milder degrees of inflammation in the tonsillar crypt occur often—a raw surface is left and particles of food become attached and undergo putrefaction. If persistent these conditions are apt to give rise to much annoyance, and the remedy lies in operative procedures. One of the most persistent of affections of the tonsil is mycosis leptothrica, or hyperkeratosis, "characterized by white projections from the crypts and orifices of the lymph follicles on the posterior and lateral pharyngeal walls and on the lateral glosso-epiglottidean folds" (Wood). This does not, as a rule, create much discomfort and becomes a source of annoyance chiefly when discovered by the patient.

I saw a young woman with this affection, who had been mistakenly quarantined for diphtheria, and when the bacteriologic report was negative the suggestion of tuberculosis was made. She came in great excitement but left in high glee with a paper marked "mycosis leptothrica" to show her attending physician. In this case a complete cure was obtained by extirpation of the tonsillar mass in a much more rapid manner than the tedious one of cautery to the individual growths. We are accustomed to view this affection among the minor ones, but Metzner[3] reports a case with fatality.

[2] Bull. de laryngol., otol. et rhinol., 1903, vi, 35.

Cartilage and bone formation of the tonsil are by no means frequent and cases have been recorded of recent years by Reitmann,[4] Compaired,[5] Newcomb,[6] Genter,[7] Ruckert,[8] Schweitzer,[9] Carter,[10] Halkin,[11] Landa,[12] Scheven,[13] and Anders.[14] The latter reports a tonsillolith weighing 147 grains. Schweitzer[9] found bone and cartilage foci in 11 of 33 bodies examined. There were several such in one and the same tonsil and a transition of the foci into connective tissue was often noted. It is not a congenital disturbance, but is due to a metaplasia of the connective tissue into cartilage and bone as a result of previous inflammation. Microscopically there is found atrophy of the lymph adenoid tissue and connective tissue proliferations. Total extirpation is advisable.

Of the benign growths occurring in the tonsil, in which complete extirpation is advisable, Mancioli[15] and Glas[16] have presented monographs. The latter records five cases, two of fibroma, one polyp of mucous glands, two teratoid new growths, and one a lymph vessel ectasia. Primary sclerosis is described by Glas[17] and Steiner.[18] Papillomata, true and false, are presented by Yearsley[19] and Tweedie[20] showed a tonsil apparently composed of a mass of papillomata. Blanc[21] reports a polyp of the tonsil and a dermoid polyp is reported by Angier and Lavrand.[22] Teratoid growth of an interesting nature is noted by Iwata[23] and Fullerton.[24] Lipoma of the tonsil is recorded by Theisen,[25] Deile,[26] Zolki,[27] and Sommer.[28] Epithelial cysts of the tonsil are recorded by Degny,[29] and Wright[30] in his usual thorough manner describes cysts in lymphoid tissue. A lymphoid tumor extirpated and cured is reported by Lavrand.[31] Excision of a tonsil affected with primary syphilis has been done by Wroblewski,[32] a procedure I hardly feel warranted in advising. Greene[33] has removed diseased tonsils and adenoid tissue to rid the throat of diphtheria bacilli. The malignant diseases of the tonsil, endothelioma, epithelioma, sarcoma, lymphosarcoma, and carcinoma, require more than extirpation of the tonsil and do not belong to the conditions under discussion.

The subdivision of this second class is constitutional affections entering the system by way of the tonsil and produced by tonsillar disease.

Ten years ago I presented my views and those of others on the tonsils as portals of infection,[34] and stated that certain forms of infectious diseases follow closely on tonsillar affection, the same micrococci existing in the former as in the latter, and hence are mentioned as being tonsillar in origin. The list of diseased states that follow the various forms of angina has become formidable and we should regard the tonsillar affection with the import its existence requires. A year ago I[34] stated that infection in rheumatism and gout enters the system by way of the mouth, the opinion of the majority being that the chief point of entrance is the tonsil. A careful study of the voluminous literature of the subject does not change in any way the opinion then expressed, and for the requirement of the matter under discussion we quote from Adler:[35] "I would most emphatically endorse the position taken regarding the treatment of the tonsils, viz., that inflamed tonsils are a source of danger to the individual possessing them and that recurrent tonsillitis constitutes a positive indication for the ablation of the tonsils."

The masterly essay of Wood[36] on the importance of the upper respiratory tract in the etiology of cryptogenetic infections, especially in relation to pleuritis, is so recent and contains so full a reference to the important literature of the subject that repetition would be superfluous. He calls attention to the following affections associated with or dependent on tonsillar disease: Tuberculosis of the lungs with and without tuberculosis of the tonsils, rheumatism, general infection, nephritis, tenosynovitis, endocarditis, bronchitis, pneumonia, pleurisy, appendicitis, jaundice, phlebitis, meningitis, parotitis, skin and eye lesions.

The relation of angina tonsillaris and appendicitis has been discussed editorially in THE JOURNAL of the American Medical Association,[37] and Weber[38] reports a case of these conditions occurring.

P. K. Brown[39] refers to a case of nephritis after tonsillitis and says that the kidney complication is more frequent than is generally known, and he mentions three other cases, apparently traceable to diseased tonsils. These are acute mania, septicemia, and leukemia. The *New York Medical Record*[40] quotes Hougarde as describing six cases of acute nephritis associated with hypertrophied tonsils. One was mentioned as showing the good effects of a tonsillectomy on the nephritis. H. B. Gardner,[41] writing on secondary effects on the system which may be produced by chronic enlargement of the tonsils, says the hypertrophied tonsils may be a causal factor for varicose veins of the leg and hernia. Regarding the relation of the tonsil to hyperthyroidism I quote from a recent article on "Some Relations of the Thyroid Gland" by S. P. Beebe.[42] He says:

> In another group of cases there is fairly good evidence that the disturbance of any infectious disease, notably tonsillitis and typhoid, has been the primary event in the abnormal thyroid physiology. It has been customary to explain these cases by supposing that the thyroid is called into unusual activity in order to combat the toxemia in the disease and that from this beginning the vicious circle is continued. There is no doubt that hyperthyroidism often follows tonsillitis, but Beebe believes this may follow as a result of a vasomotor dis-

turbance rather than to suppose that the altruistic action of the thyroid has continued to an ungovernable condition.

In all of these conditions cure is often found to follow tonsillar removal, but the surest and safest guide will be, bearing in mind the many lasting conditions that follow on a diseased state of the tonsil, to study these organs carefully and by prompt extirpation prevent the *inroads of these dread disorders.*

With this presentation of the subject I feel warranted in presenting the following conclusions:

Unusual hypertrophy, including the submerged and degenerate variety, recurrence of inflammatory affections, including benign growths, or evidence of a diseased *state of the tonsil prejudicial to health, makes it* imperative on physicians to advise thorough extirpation of the tonsil.

25 East Seventy-seventh Street.

REMOVAL OF TONSILS*

NORVAL H. PIERCE, M.D.
CHICAGO

Without going into the consideration of anatomic details, I will proceed at once to the discussion of some of the various methods of dealing surgically with diseased tonsils. The complete removal of all tonsillar tissue that is at the time or is liable in the future to become diseased, with the incurrence of the minimum danger from hemorrhage or infection, constitutes an ideal to which we should strive in our operative technic. Any procedure short of this falls short of the ideal. At the same time circumstances arise which will not permit of the more [illegible] methods, in which case we adopt one [illegible] for the destruction of the lacunæ. The best of these consists in slitting the lacunæ which may be reached by means of a bent knife, and afterward cauterizing them with nitrate of silver fused on a copper probe daily until as many as possible are made to heal open. This is followed by benefit in a great number of cases, but is never permanently satisfactory. The use of the cautery (ignipuncture) *for this purpose* or for destroying or removing tonsillar tissue, is not nearly so satisfactory as the cold methods, inasmuch as the pain at the operation and the reaction is very much greater and the results are not so satisfactory. If the tonsil is to be removed we may proceed in various ways.

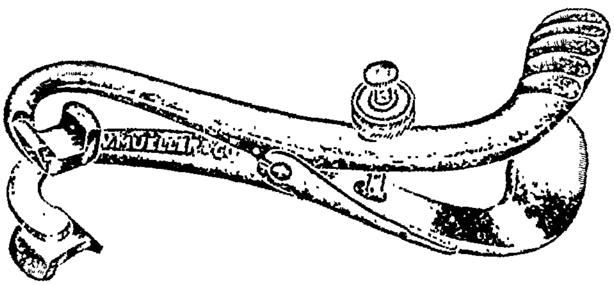

Fig. 1.—Pierce's mouth gag. Spring ratchets are apt to get out of order or slip; they do not allow the slight adjustments of the screw that is used for the setting mechanism of this gag.

In all cases there should be a period of preparation. It is a great mistake to underestimate the gravity of tonsillar excision. It is not an operation that should be performed at the office; it is necessarily a hospital operation, whether performed under a general or local anesthetic. The patient should preferably be sent into the hospital the day before the operation is to be performed. A careful history should be taken and general physical examinations made, together with a microscopical and chemical examination of the urine. Tonsils should not be operated on while in a state of inflammation, as this is the cause of the majority of severe hemorrhages following their ablation. Women and girls should not be operated on while menstruating. Special care should be taken to detect the status lymphaticus and to elicit a history of hemophilia; and on inspection we should be careful to note the presence of pulsations in or about the tonsils. This leads me to say that we can *only partially ascertain what we wish to know regarding* the tonsils by inspection, which should always be supplemented by palpation. In this way we can ascertain deeper pulsations, the extent of the tonsils as well as the presence of bony or other deposits in the tonsil, *and the presence of a projecting styloid process.*

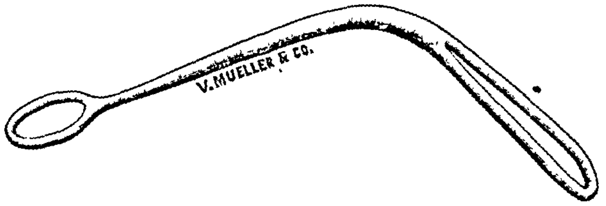

Fig. 2.—The advantage of this tongue depressor is that it does not crowd the tongue backward, thus interfering with respiration, as does the broad depressor.

A course of calcium chlorid for a week preceding the operation has an influence in reducing the hemorrhage at the time of operation. If there is doubt as to the coagulability of the blood, its index may be ascertained. The bowels are emptied by a cathartic the night before, and if necessary by an enema in the morning; no food is taken on the day of operating if the operation is performed in the morning and only a very light breakfast if performed in the afternoon. A hypodermic administration of a dose of atropin a half-hour before the operation in adults and older children, or of belladonna in young children, will decrease the amount of secretions during anesthesia.

ANESTHESIA

General Anesthesia.—This should be employed in all young children and in nervous adults. If adenoids are to be removed at the same time, as is usually the case, I am strongly of the opinion that deep narcosis is urgently to be advised. For this purpose, ether is used on account of its unquestionably greater safety over chloroform, although it has some disadvantages. The administration of the anesthetic may be by means of a pipe introduced around the corner of the mouth, the ether fumes being pumped from a receptacle by means of a double rubber bulb, or a closed mask may be used. The closed mask does very well if the anesthetist will

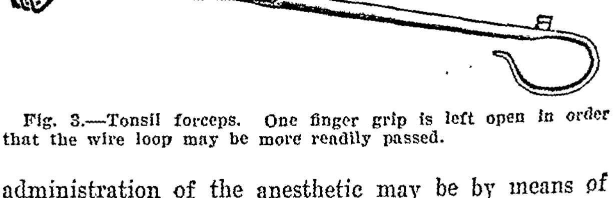

Fig. 3.—Tonsil forceps. One finger grip is left open in order that the wire loop may be more readily passed.

---

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

reapply the anesthetic whenever the operative procedures are interrupted, if only for an instant. The open or gauze mask is not nearly so satisfactory as the closed one, because with the former a deep anesthesia is very much more difficult to maintain. The advantages of deep, tranquil anesthesia can not be too strongly insisted on. There is greater safety for the patient; the operation proceeds much more rapidly, and with greater exactness. It must be remembered that the deep pharyngeal reflexes are among the last to disappear, and we may proceed with an operation on the mastoid or with an amputation of a limb at a much earlier stage than is best for a tonsil or any throat operation.

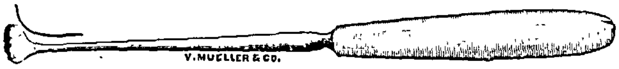

Fig. 4.—Pierce's tonsil knife.

In order to aid in the abolition of the deep pharyngeal reflexes, after the patient has become relaxed, we may swab the tonsillar regions with a 10 per cent. cocain in 1 to 1000 adrenalin solution. Occasionally, we may have cases in which ethyl chlorid may be a sufficient anesthetic, but these are rare. There can be no dissecting done, and the tonsillar tissue must be of that pedunculated type which may be properly removed by means of a tonsillotome. Nitrous oxid is less satisfactory than ethyl chlorid.

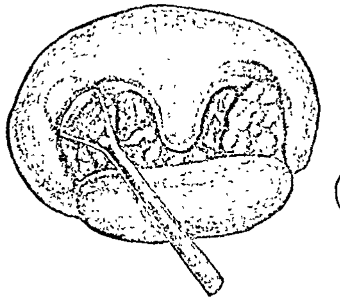

Fig. 5.—Pierce's tonsil knife being inserted into the supratonsillar space.

LOCAL ANESTHESIA

This is reserved exclusively for older children and adults who can be controlled. The tonsil, posterior and anterior pillars, posterior wall of the pharynx, and arch of the velum are painted over with a 10 per cent. cocain solution. This is also rubbed into the crypts and supratonsillar space, by means of cotton wrapped on a bent cotton applicator. The cocain solution is followed by adrenalin solution, 1 to 1000, applied over the same area, and when a surface anesthesia has been procured, a 1 per cent. cocain solution, containing two drops of 1 to 1000 adrenalin to the ordinary hypodermic syringeful is injected on each side at three points, namely, at the base, at the middle, and at the upper confines of the tonsil, ascertained by means of palpation; from three to five drops at each point is sufficient. I have found local anesthesia in tonsillar work, except in those cases of pedunculated growth, more or less disappointing. Especially is this true in cases in which there has been considerable previous inflammation, and in which the submerged tonsil is encased in plastic fibrous tissue. This is particularly true when the snare is used, so that it is better to use a cutting instrument, the knife or scissors, such as the Robertson, in removing tonsils under local anesthesia.

When the general anesthesia is complete, a mouth-gag is inserted in the left side of the mouth well back. The mouth gag may become a source of great annoyance if improperly tended. If the jaws are opened too wide, respiration is interfered with, especially in young children, and its constant or inopportune displacement is exasperating. If there are but two assistants the anesthetist should have full charge of the mouth gag from the beginning to the end of the operation and should be held responsible for its proper manipulation (Fig. 1).

POSITION OF THE PATIENT

The position of the patient is an important matter. Doubtless, operators become accustomed to various positions as they become accustomed to different instruments, but after an experience extending over a number of years with the various positions, I have adopted the one to be described. The patient is placed on the right side, with the right arm crooked beneath the body, and the right leg semiflexed. The right side is chosen as throwing less of a burden on the heart of the patient. A sand-bag is put under the head which is drawn over close to the edge of the table. Another large sand-bag is shoved snugly against the back in order to keep the patient from rolling backward, or better, a nurse is employed to keep the patient balanced on the right side. In this position, safety is insured against the danger of blood or excised tissue getting into the larynx.

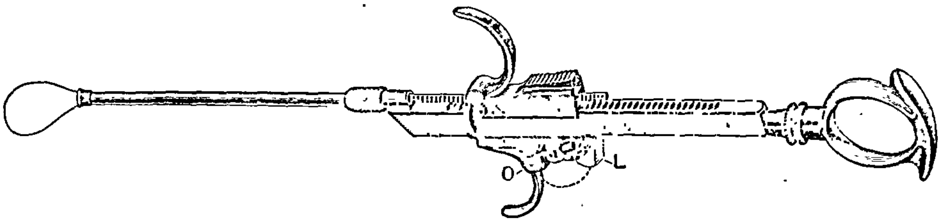

Fig. 6.—Pierce-Mueller tonsil-snare. The new snare consists of a flat steel bar having at its distal end a strong steel cannula with reinforced end. Notches are cut in the upper side of the steel bar and the lower side is milled out and contains the threaded rod for écraseur attachment. On this steel bar runs a carriage supplied with two half-curved finger-holds. In the upper portion of this carriage is an arrangement like a windlass and by pulling back the carriage (with wire-carrier and snare loop) this windlass drops into the notches in the bar and securely locks it, and prevents it from receding and letting loose the object once grasped.

On the lower side of this carriage is a lever in connection with a chuck, and this (when pulled backward) grips into the threaded rod which rests in the milled out part of the flat bar and converts the snare into an écraseur.

This new snare has none of the many springs of the older models of this type and there is very little chance for the instrument's getting out of order.

To load this snare push the carriage forward as far as it will go, by pressing on knurled lever A, set the wire-carrier so that the two holes only for the wire will show and place the ordinary snare loop in the wire-carrier. After placing the loop over the tonsil you may either pull right through, or,-as the carriage locks itself by means of a ratchet, you can stop at any point. In order to set the snare as an écraseur, pull the lever below the carriage from O (open), to L (locked), then turn the ring at the end of the flat bar until the tonsil comes off. To put snare in position for reloading, unlock it and push forward on lever A.

TECHNIC

The operator is seated so that his line of vision is on a line with the patient's mouth. This position may be acquired either by raising the table on blocks, or by the operator sitting on a low stool. The light is thrown into the field of operation by means of a mirror, reflecting the light on a movable bracket, or by means of an electric lamp of some form carried on the operator's head. A small tongue depressor (Fig. 2) is introduced, and the tonsil seized in a vulsellum forceps, the extremity of which is bent nearly at right angles to the shaft

(Fig. 3). One jaw is fastened in and beneath the base of the tonsil, and the other as far as possible into the supratonsillar fossa. By means of a knife the tonsil is freed from the supratonsillar roof and from the upper two-thirds of the anterior and posterior pillars. Various forms of knives have been used for this purpose. In the last three years I have used exclusively one which I have designed and found very satisfactory (Figs. 4 and 5). It is introduced with the blade upward into the supratonsillar space, and carried in this position first beneath the anterior pillar, and then downward along the posterior pillar. The tonsil is then twisted out of its bed. Frequently no more detachment is necessary. The whole tonsil up to its capsule can be dislodged. If this is not the case, however, by means of a scraping motion away from the gland the tonsil is dissected loose from its attachments, following along the line of demarcation, between the tonsil and the peritonsillar tissue. The moment the tonsil is delivered from the supratonsillar space, the snare is applied, being careful to get above and below the tonsil (Fig. 6). At this point it is essential to see that the uvula has not been included in the loop. In order to guard against this accident, it is well, before applying the snare, to secure the tip of the uvula with a long hemostatic forceps.

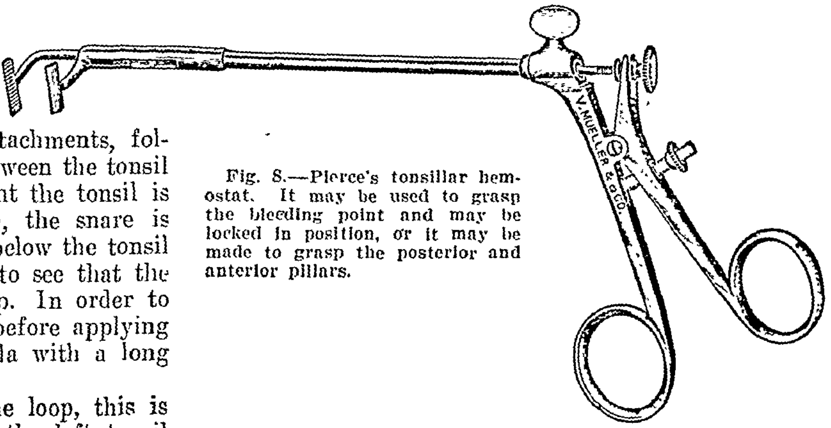

Fig. 8.—Pierce's tonsillar hemostat. It may be used to grasp the bleeding point and may be locked in position, or it may be made to grasp the posterior and anterior pillars.

When the tonsil is secured within the loop, this is tightened and allowed to remain while the left tonsil is freed. This is loosened from the upper portion of its bed in the same manner, and when the snare is tightened, we proceed with the complete removal of the right, and then follow with the left, as soon as the hemorrhage from the right has stopped. This means of hemostasis is successful in diminishing hemorrhage. If the hemorrhage continues unduly, pressure for a few minutes with a piece of gauze held in a hemostatic forceps will nearly always arrest it (Fig. 7). If properly done, the entire tonsil has been enucleated. If, however, from imperfect technic there remain portions of the tonsils, especially in the supratonsillar space, they must be thoroughly removed by means of either the snare or the tonsillar punch. Blood during the course of operation is carefully removed by an assistant by means of cotton torpedoes carried in long hemostatic forceps. Intelligent sponging is of the greatest assistance; done otherwise it may more interfere with than aid the operator.

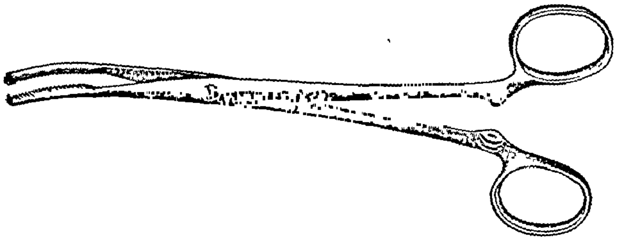

Fig. 7.—Long forceps used for sponges, which is also an effective tonsillar hemostat.

If local anesthesia is employed, the assistant should be stationed to the left, a little behind the operator, the instrument table being to the right. With a general anesthesia these positions are reversed if there is but one operating assistant, as he must manipulate the tongue depressor. If there are two operating assistants, and this is more to be desired, one should stand to the right and attend to the tongue depressor and mouth gag, while the other assistant sits behind and a little to the left of the operator and presides over the sponges and instruments—anticipating the operator's needs.

At least two assistants are necessary for the expedition and successful removal of tonsils under general anesthesia, one for the anesthetic, the other to sponge, hold instruments and attend to tongue depressor. Both require special training. The anesthetist should be able to recognize the stage of anesthesia at which the operation is best performed and to keep the patient constantly in this stage. This requires, especially in case the closed cone is used, constant vigilance, the anesthetic being reapplied whenever the operator's procedures are interrupted. Nothing is so annoying in tonsillar work as an improper anesthesia—it causes delay, adds danger and tends to render the work imperfect.

Do not be too hasty in allowing the patient to be removed from the operating-room. Carefully inspect the field just before the patient's removal for hemorrhage, and for the presence of tonsillar tissue that might have been overlooked at the operation. In case pressure does not control hemorrhage, careful search should be made for bleeding points. These are usually found at the middle third of the wound, and consist of the tonsillar artery or the venous plexus situated at this point, and may be controlled by (a) torsion with hemostatic forceps; (b) putting in a figure-of-eight stitch; (c) sewing the anterior and posterior pillars together with a pledget of gauze held down on the tonsil by means of the stitches or by means of Pierce's tonsillar hemostat, held *in situ* (Fig. 8). The Mikulicz compressor is a most cruel instrument, and should scarcely be employed. The pain it causes is excruciating and, if left on for any considerable time, it is liable to form a slough which may be so extensive as to form a fistula from the pharynx to the exterior or cause dysphagia and paralysis. Hemorrhages from tonsillar operations do not come from the external or internal carotid. These vessels are safely out of the way. There may, however, be a loop of the lingual thrown up into the base of the tonsil. In this case severe hemorrhage results, but it can be controlled either by means of a hemostat or a deep ligature. Chevalier Jackson's experience with tonsillar hemorrhage must be unique, as I have not yet seen a case which demanded ligation of the external carotid.

I have employed the method described for the past six years in cases of large, globular imbedded tonsil. For pedunculated tonsils, which project into the oral cavity, I do not hesitate to recommend the old Matthieu tonsillotome. The work is done rapidly, neatly and completely if the instrument is properly used. Instead of a snare, Casselberry is very dextrous in the use of the Matthieu tonsillotome, from which the fork and tripping mechanism has been dismounted. It is surprising how this instrument, after the tonsil has been detached from the pillars and the supratonsillar space, will follow the capsule; but in my hands it is more cumbersome than the snare, and does not so surely follow the capsule. The snare, when properly placed, really peels the tonsil from its bed. For long, thin, small tonsils, which are occasionally the seat of cholesteatomatous disease and cause fetor *ex ore*, the scissors are better adapted, after the method of Robertson, particularly when local anesthesia is employed.

After the operation, the patient should be kept in the hospital and in bed for from twenty-four to forty-eight hours. Food during this time should be liquid or semi-solid, without condiments. A gargle should be administered the day after the operation, and continued until the wound has entirely healed. For this purpose I recommend the following:

℞.	gm. or c.c.		
Salicylic acid	10		ʒiiss
Spirits of nitrous ether	15		℥ss
Alcoholic solution formal. (1-10)........		or	
Alcohol; āā	30		℥i
Oil of gaultheria			
Oil of caryophyl, āā....................	15		ʒss
Glycerin, q. s. ad.	120		℥iv

Sig.: Half a teaspoonful to half a glass of hot water, and gargle every two or three hours.

If pain is complained of, an ice-bag may be applied to the neck. Allowing the patient to chew bits of ice is not to be recommended, as the motion of the pharynx in swallowing and sucking is liable to perpetuate bleeding.

ADENOID OPERATIONS *

FRANCIS R. PACKARD, M.D.
PHILADELPHIA

The preliminary report of the Anesthesia Commission of the American Medical Association[1] shows the splendid results which the profession may confidently expect from its labors, and indicates likewise the vast scope of the field on which it has entered. It would seem presumptuous on my part to undertake any individual efforts in the study of the anesthesia problem at the present time, when we know that the whole subject is being so carefully and thoroughly studied. My justification for the following remarks, however, is to be found in the fact that, in operations within the nasopharynx and throat, there are certain peculiar problems which present themselves forcibly to the operator and render it imperative for him to understand them thoroughly, not only from the standpoint of the effect of the anesthetic on the safety of the patient, but also with a view of facilitating the proper performance of the operation.

As a general premise to the remarks in the following paper, I would state that, in my opinion, tonsil and adenoid operations in children and young persons below the age of 18 should practically always be done under a general anesthetic. In patients over 18 years of age, if they have sufficient self-control and their cooperation can be secured, I prefer to operate with local anesthesia by cocain.

There are certain general statements which may be regarded as true of all operations in which a general anesthetic is employed:

1. The personal equipment of the anesthetist is by far the most important factor in any operation under a general anesthetic. This would include his experience and judgment and all the other factors which go to give him a claim for ability to administer the drug. This personal equipment of the anesthetist is of so much importance that, to my mind, it almost overshadows the question of which is the safer anesthetic to use, and although, as I shall state further on, in my opinion, the dangers of chloroform are so much greater than those of ether, if the anesthetist is used to administering chloroform, and I feel that he could give it bettter than he could administer ether, I would prefer him to use the anesthetic which he was accustomed to giving.

2. The patient should be under observation or control, whenever possible, for at least twelve hours before the operation, and after it until he has completely recovered from the effects of the anesthetic. It is very hard, particularly in children, to be sure that patients will refrain from food before taking an anesthetic. Twice I have nearly lost a patient because of his having eaten shortly before the operation. In one case a child stopped breathing because a piece of bacon became impacted in the larynx. In the other case a child's tonsils and adenoids had been removed, when he was observed suddenly to turn blue. No obstruction was found in the larynx, but artificial respiration, with the administration of oxygen, was maintained for fifteen minutes before the child took a natural breath. He then vomited an enormous quantity of undigested food. These cases illustrate the two ways in which the ingestion of food before the administration of an anesthetic is a source of danger: (1) by the lodgment of a piece of vomitus in the larynx, (2) by pressure on the diaphragm from a distended stomach.

3. Operations under general anesthesia should be done, whenever possible, in a hospital or in the patient's home and not in the physician's office. The extreme risk of allowing the patient to go out just after recovering from ether or chloroform has been repeatedly demonstrated.

4. If the operation is performed in a house or elsewhere than in a hospital, oxygen and other restorative means should be provided beforehand. I now always make it a practice, when operating in private houses, to have an oxygen apparatus at hand, and I believe that at least on one occasion when a child took ether badly its life was only saved by the use of oxygen. A tracheotomy tube and the few other instruments necessary for the performance of a tracheotomy are always carried in my bag when operating at a patient's home. In a case which occurred in the practice of one of my colleagues a piece of tissue from the throat completely occluded the larynx and the operator was obliged to perform an immediate tracheotomy in order to save the child.

5. Although there is a very prevalent impression in the profession that mixed anesthesia, in which the narcosis is started with one anesthetic and maintained with another, is dangerous, this would seem to be contrary to the facts according to available statistical tables. Thus W. Estell Lee[2] analyzed the statistic of the anesthesias at the Pennsylvania Hospital for a period of five and one-half years. In that period ether was given alone or in combination 5,592 times, and there were three deaths occurring in this number. All these fatalities occurred

---

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

[2] Ann. Surg., November, 1908.

among the 1,444 cases in which the ether was given alone. The same statement applied to the deaths which occurred under ethyl chlorid in the institution. Ethyl chlorid was given as a general anesthetic, alone or in combination, 5,575 times, with five fatalities. All these deaths occurred among the 947 cases in which the ethyl chlorid alone was administered. In carefully examining other large compilations of statistics, such as Gurlt's, one is impressed with the same fact.

There are several reasons which render the subject of anesthesia in tonsil and adenoid operations one of the greatest importance:

(*a*) Children who suffer from pathologic conditions of the faucial and nasopharyngeal tonsils are apt to present the condition which the French term "*lymphatisme*" and which we generally term the "status lymphaticus." The sufferers from this diathesis are notoriously bad subjects for the administration of any general anesthetic. W. Humes Roberts[3] summed up the views which are now generally accepted by pathologists in regard to that condition, namely, that there is a general enlargement of the lymphatic structures associated frequently with hyperplasia of the thymus gland and accompanied by a hypoplasia of the circulatory apparatus. Sudden death may occur in patients who suffer from this diathesis from very slight causes, such as shock, emotional or physical, frights or slight injury. Dr. Roberts reports four cases of death from the administration of chloroform for the removal of tonsils and adenoids, in Los Angeles. In the only case in which autopsy was permitted there was a marked status lymphaticus.

(*b*) The mechanical obstruction to proper respiration offered by the presence of adenoids and enlargement of the faucial tonsils is such that the inhalation of the anesthetic is interfered with so that its administration is prolonged and the amount necessary sometimes very large. This difficulty is also increased by the presence, in the throat in most of these patients, of great quantities of mucus. In several cases I have tried to overcome this difficulty by the administration of small doses of atropin some hours before the ether. The results, however, were not very satisfactory, as the dose necessary to induce dryness of the mucous membrane was found to be too large to be consistent with safety.

(*c*) Another difficulty encountered in the administration of a general anesthetic in these cases is the problem of not interfering with the operator. To obviate this I have my patients very thoroughly anesthetized before I undertake to do any work. After the operation has begun it takes so short a time to finish it that if the patient is completely under at the start, he seldom requires the further administration of the anesthetic before its conclusion. The best method of giving ether or chloroform, in my opinion, is the so-called drop method on gauze, except in patients who require any prolongation of the anesthesia, when I have the anesthetist change to the vapor method, passing the ether through warm water in a wash bottle by means of a bulb compression apparatus. The one designed by Dr. Pynchon, of Chicago, has proved satisfactory for this purpose.

The position in which the patient should be placed during the operation has been, and still is, a subject on which opinions differ largely. I always operate with the patient in the dorsal decubitus, with the head dropped somewhat over the end of the table. There is no doubt in my mind that the upright position adds greatly to the danger of ether and chloroform, and also that in the upright position the amount of blood and mucus which flows into the larynx or esophagus must be greater than when the head hangs lower than the body. Again I believe that the upright position adds to the risk of a piece of detached tissue entering the larynx and possibly causing dangerous obstruction. The danger of an aspiration pneumonia is by no means imaginary and no pains should be spared to lessen such a mischance.

As to the anesthetic for use in the operations on tonsils and adenoids, I have no hesitation in declaring my decided preference for ether. Some years ago Dr. Hinkel,[4] of Buffalo, read a valuable paper before the American Laryngological Association, in which he showed that there had been nineteen fatal cases from the administration of chloroform, one from A. C. E. mixture, and none from ether in these cases. I know personally of two unreported cases of death from chloroform and of not a single ether fatality in Philadelphia, in which the anesthetic was given for the removal of tonsils and adenoids. When it is considered that in Philadelphia ether is used in an overwhelmingly larger number of cases than chloroform, this seems a significant fact. I am aware that many will reply that in places where chloroform is more generally used there are fewer deaths, but I believe that only men who are familiar with its administration would dare use it in a city where its use is so generally deprecated. Statistics the world over show that the deaths from chloroform vastly outnumber those from ether; thus Gurlt[5] reports the following statistics:

	Cases.	Deaths.	
Chloroform	201,224	88	1: 2,286
Ether	42,141	7	1: 6,020
Chloroform and ether	10,162	1	1:10,162
A. C. E. (Billroth's)	5,744	1	1: 5,744
Ethyl bromid	8,967	2	1: 4,483

Seitz's figures, reported by W. J. McCardie,[6] are as follows:

Pental	1 death in	200	anesthesias
Chloroform	1 death in	3,000	anesthesias
Ether	1 death in	5,000	anesthesias
Ethyl bromid	1 death in	8,000	anesthesias
Ethyl chlorid	1 death in	16,000	anesthesias

W. H. Luckett[7] gives the following statistics:

	Cases.	Deaths.
Chloroform	4,263	1
Ether	4,673	0
Chloroform to ether	141	0
Ether to chloroform	116	0
Chloroform and ether	164	0
Cocain and chloroform	6	0
Cocain and ether	10	0
Cocain	706	0
Nitrous oxid	142	0

We should remember, as I have before stated, that tonsil and adenoid patients show a distinct tendency to take any anesthetic badly, rendering it imperative that the safest possible should be chosen.

Nitrous oxid anesthesia is of such short duration that its usefulness is decidedly limited. I have had no opportunity to try it used in conjunction with oxygen so as to prolong its effect.

Ethyl bromid has resulted fatally in so many cases in proportion to the number of times it has been used

that I never considered it right to employ it. It undergoes decomposition very easily and rapidly, and when decomposed is a very dangerous poison.

Ethyl chlorid I have used many times, especially in conjunction with ether, at the Pennsylvania Hospital. Although it is a rapidly acting anesthetic and gives rise to practically no unpleasant after-effects, its use is attended by at least one great drawback. If administered for any length of time it induces great rigidity of the jaws, which seriously interferes with the introduction of the gag. It also seems to me that it does not lessen the sensitiveness of the mucous membrane as do ether and chloroform. The patient is apt to cough and gag even when apparently unconscious.

I have appended to this article a list of the deaths attributable to the use of general anesthetics in the removal of tonsils and adenoids. By it will be seen that out of 29 fatal cases 26 deaths were attributable to chloroform, 2 to ethyl chlorid and 1 to a combination of chloroform and A. C. E. mixture. The oldest patient was a woman of 20, the youngest a child of 3. Of the cases in which sex was stated, there were 12 males and 9 females.

I desire to express my indebtedness to Dr. E. J. Stein, of Philadelphia, for much valuable assistance in the compilation of the bibliography accompanying this article. Although Dr. Stein made a careful search of French and German literature, he was unable to find any deaths recorded as the result of the use of a general anesthetic in operations on tonsils or adenoids.

POSTOPERATIVE TONSILLAR BLEEDING

ITS SURGICAL CONTROL, WITH MENTION OF CASES *

LEE COHEN, M.D.
BALTIMORE

The operation on the faucial tonsils at this time may be said to be in a transitional stage from that of incomplete to complete removal. The importance of this subject prompted me to make known some of my ideas and experiences connected with the operation. My first intention was to discuss the entire subject in a general way, and the ideas of a number of the leaders in this Section were asked for in a circular letter addressed to them. I desire here to express my appreciation of their hearty and prompt replies. Our Executive Committee, realizing the magnitude and great importance of the tonsil operation, very wisely decided that a symposium would best serve the purpose of bringing forth a comprehensive and general discussion. I have, therefore, the honor of saying a few words about postoperative tonsillar bleeding.

Hemorrhage from the removal of the faucial tonsils varies greatly, the primary bleeding when all goes favorably amounting to less than an ounce. In some cases, however, the bleeding reaches alarming proportions. The term "alarming proportions" is difficult to define, since a loss of blood which some operators would look on with indifference might cause others great concern. Again a loss of from four to six ounces of blood in some cases might be considered alarming if the patient were frail or young, whereas in a strong, robust individual a loss of this amount of blood could work no material harm other than prolonging convalescence.

Generally speaking, female patients beyond puberty bear loss of blood better than males because of their propensity for more rapid blood-making. When confronted with a freely spurting vessel it is impossible to determine how great may be the loss of blood should it not quickly and effectually be controlled. I can recall my feeling of dismay when first brought face to face with a real bleeding of this kind, but that first case of extreme bleeding proved to be a blessing in disguise, for it forced me to adopt measures whereby I may now feel reasonably secure from any very serious effects of tonsillar bleeding.

I am told by such men as Welty, Stucky, Richards, Robertson, Todd[1] and others that the loss of blood following a complete removal of the tonsil in its capsule is less than after the old method of tonsillotomy with the guillotine. On the other hand, Jackson, Thomas, Vaughan and others,[1] while advocating such complete removal, claim that the loss of blood is greater therefrom.

A fact worthy of note is that, of the 54 cases of alarming bleeding tabulated by Smith[2] and Wright,[3] the tonsillotome in some one of its many forms was employed in 34; and it was also used to remove the tonsils in at least 3 of the 6 fatal cases found by them in the literature from 1868 to 1904, the method of removal in the other 3 fatal cases not having been mentioned. In the 4 more recent fatal cases, reports of which I have been able to collect, the tonsillotome only was employed.

My experience has been that there is a greater tendency to bleed in tonsillectomy than in tonsillotomy, because, in the former, vessels are cut before they subdivide into the terminal filaments and nearer to the source of the large arteries from which they are given off. But I have adopted the complete removal because of the better results thereby obtained, and in performing this operation I have learned how bleeding can be controlled, so that I now feel that the loss of blood from my complete operation is generally much less than it formerly was in performing tonsillotomy.

Two of my cases which I wish to report will illustrate clearly the difference between the old and nonsurgical method of controlling hemorrhage and the more recent and effectual one.

CASE 1.—*Operation.*—A. K., a healthy woman, aged 23, was operated on by me in my office on Jan. 28, 1908, at 4 p. m., under local anesthesia. Both tonsils, which were perhaps the largest I have ever seen, were removed *en masse* with the knife and vulsellum. Bleeding from both sides at the time of the operation was quite profuse, the bleeding on the left side being effectually stilled by pressure with cotton soaked in Monsell's solution. On the right side I was obliged to use Boetcher's hemostat.

Postoperative Hemorrhages.—The patient was removed from my office to the Hebrew Hospital in the evening with the clamp still in position. The hemostat was removed at 10 p. m., the cotton pledget being left in position for nearly three days. No bleeding on removal of cotton. The following, or fourth day, patient left hospital. Nine days after the operation, at midnight, there was a slight bleeding from the right side, this being easily controlled by the use of ice internally and externally. There was no further loss of blood until the following afternoon at 3:30, when it was again necessary to make use of the pressure hemostat. The patient was then sent back to the hospital, and on attempting to remove the clamp at 11 p. m., hemorrhage recurred, making it necessary to replace it. The following morning, February 8, at 2 a. m., a slight bleeding was again noticed, but it was controlled easily by pressure and the use of ice. At 4 o'clock the same day there was again a slight loss of blood, at which time a heavy silk suture was passed deeply through the upper portion of the tonsillar pillars, over the point from which the bleeding seemed to come. For the following twenty-four hours there was no bleeding, and the patient's condition was very satisfactory. Late the next afternoon, February 9, twelve days after the operation, very active hemorrhage commenced, in spite of the suture. Mere pressure had no effect, so the hemostat was again placed in position, bleeding being controlled after a few minutes. At 7 p. m., the clamp slipped, and before it could be replaced a pus basinful of blood was lost.

Control of Hemorrhage.—The patient now being quite weak, we realized that some very radical measures must be adopted at once to avert a fatal issue. She was therefore placed on the operating table at 7:30 p. m., firm pressure being made over the common carotid artery to prevent further bleeding. A roll of iodoform gauze about the size of the tonsil removed, saturated with 1 to 1,000 adrenalin chlorid solution was placed in the tonsillar fossa, and firmly held with a large Kelly clamp by an assistant. A continuous suture was then placed in the pillars of the fauces from the soft palate down to the base of the tongue, a curved Hagedorn needle, placed at a right angle in a plain needle-holder, being used for this purpose. No anesthetic was used for this operation, on account of the weak state of the patient. The time consumed in the work was about half an hour. The pulse was small —about 160 to the minute, and the general condition of the patient was very bad. Two salt infusions of about a pint each were given, one at once and another during the night. There was not a drop of blood lost from this time on. The suture was removed four days later and the gauze pledget allowed to remain one day longer. The tonsillar fossa on removal of the gauze looked very clean, and the patient steadily improved, leaving the hospital in excellent condition on February 21, fifteen days after her last admission.

The lessons learned from this case have been most valuable: First, I believe the secondary bleeding was directly caused by the sloughing process following the primary use of Monsell's solution in the tonsillar fossa. I would never again sanction the use of this agent in controlling hemorrhage from the tonsillar region. Second, by permitting repeated recurrences of the bleeding over so long a period of time the patient's life was almost lost. In a similar case I would adopt radical measures at once. Third, had the primary bleeding in this case been managed in the same surgical manner that we employ to-day, we should have been spared all our trouble and anxiety and the patient the danger and discomfort to which she was subjected.

A very interesting case, and one which was managed in a manner somewhat like my own but which ended fatally, has been reported by Damianos and Hermann[4] of Vienna. There are many points in this case worthy of note, and I therefore take the liberty of giving it in detail:

CASE 2.—The patient, a strong, robust man, aged 23, was operated on in one of the dispensaries, with Fahnstock's tonsillotome, on the afternoon of Oct. 9, 1901. An hour and a half later he was brought into the Vienna surgical clinic bleeding profusely from what appeared to be an artery of large caliber. Digital pressure, within and without, over a period of an hour and a quarter, controlled the hemorrhage for about an hour. When it recurred a Mikulicz-Störk compression clamp was applied until the following morning. No further bleeding occurred for three days. On October 13 it was again necessary to apply the clamp to stop bleeding. Removal of the clamp twenty-four hours later, the 14th, was followed by more bleeding, necessitating its further immediate use. No further hemorrhage occurred until the 16th—two days later—when it was once again necessary to make use of the compression clamp. Its removal twenty-four hours later was not followed by bleeding, but there were signs of sloughing at the points where the pressure had been too continuously made by the clamp. A fistula leading from the throat within, through the skin, permitting fluids to escape on swallowing, made its appearance on the 18th, a day later. On the night of the 22d, following an intense paroxysm of coughing, a profuse hemorrhage occurred. the patient losing almost a liter of blood within a few minutes. This was controlled by prolonged digital pressure, but the patient sustained another, though smaller, loss of blood during the night. The following morning, the 23d, the common carotid artery was ligated, but the patient died at 4:30 o'clock in the afternoon, sixteen days after the operation, not having been able to withstand the great loss of blood. Autopsy showed that a small artery arching off from the external maxillary, and running directly into the base of the tonsil, had been severed. A sound could be passed through this vessel from the external maxillary artery to the point in the tonsillar base where it had been cut.

It is clear in my mind that had this bleeding vessel been caught with the artery forceps and ligated with catgut or silk before the loss of blood was so great, the patient's life could have been saved.

To illustrate how such serious bleedings can be averted when the proper measures are used to control primary bleeding, I shall now report a more recent case occurring in one of my patients at the Hebrew Hospital:

CASE 3.—*Operation.*—M. H., a man aged 36, height 5 feet, waist measure 45 inches and weight 185 pounds (all conditions promising for much bleeding), was operated on by me under local anesthesia, Dec. 31, 1908, at 4 p. m. *There was no difficulty in the removal of both tonsils en masse in their* capsules, with the knife and vulsellum, without injury to the pillars of the fauces or exposure of muscle tissue. There was practically no primary bleeding, and the patient was required to keep in an upright position for several hours.

Postoperative Hemorrhage.—There was but the occasional expectoration of blood-stained saliva until about 9 o'clock in the evening, when the patient began to bleed profusely. He was then taken to the operating room and placed on the table. Bleeding from both tonsillar fossæ was found, more profusely from the right, however. A large spurting artery situated deep in the fossa of the right side, near the base of the anterior pillar, was pumping a steady stream across the opposite side of the throat. The bleeding was so profuse that pressure with several sponges seemed to have but little effect.

Control of Hemorrhage.—This vessel was then caught with the Jackson hemostat as quickly as possible and tied with catgut. There was another bleeding vessel of considerable size situated in the supratonsillar fossa of the same side, and this was also clamped and ligated. The patient lost perhaps in all about eight ounces of blood. Though this controlled the major part of the bleeding, there was still a tendency to ooze. The cause for this was soon found and one more artery of small size, situated deeply about the middle of the right posterior pillar, was caught and tied, also two small veins on the left side, one high up in the supratonsillar fossa, and the other in the bottom of the fossa just above the tongue. There was no further loss of blood, and the patient made an uninterrupted recovery, leaving the hospital on the third day after the operation.

From the profuse bleeding in this case we may say with certainty that had the same measures been employed to control it here as in Case 1 the outcome would have been as serious as in the former case, if not more so.

Many reasons have been offered as to why bleeding is great in some cases and slight in others. There can be no doubt that hemorrhage is more likely to occur in older subjects, but I have been forced to ligate vessels in a number of very young children. Severe hemorrhage has also been said to occur oftener in men than women. In my own experience, however, I can find no basis for this belief.

Hemophilia has been thought in many instances to be the cause of alarming hemorrhage. While no one will dispute the seriousness of an attempt to remove the tonsils in cases in which a real hemorrhagic diathesis exists, there are but few authentic cases of postoperative tonsillar hemorrhage where real proof of hemophilia can be produced. In the 150 cases collected from the literature by Damianos and Hermann,[4] only five, from the history, were thought to be hemophiles. In but two of the eight fatalities, reports of which were collected by the same authors, could this form of dyscrasia be suspected.

Among the fifty-four cases tabulated by Smith[2] and Wright,[3] three patients, all of whom recovered, were said by the operators to be hemophiles. I doubt whether even three patients would have recovered had they been real hemophiles. An undoubted hemophile was the patient whose case was reported by Dr. R. H. Johnston[5]—a boy, aged 17, who died fourteen days after three tonsillar crypts had been cauterized with the galvanocautery, from an almost continuous bleeding starting on the ninth day.

Dr. Chevalier Jackson[6] reports a case in which he saved the life of a patient after tonsil operation, performed by another physician, by ligation of the external carotid artery. Subsequent developments showed undoubted hemorrhagic diathesis, the patient bleeding to death from epistaxis at a later period.

I believe that in many of the so-called hemophiles the bleeding is due to a blood vessel having been opened by cutting and not securely tied. In the Vienna case a family history of bleeding had been elicited from the patient, and, had the autopsy not proved the vessel to have been cut, this could undoubtedly have been reported as a case of hemophilia.

Cutting of either pillar of the fauces has been mentioned as a frequent cause of hemorrhage; many believe this to be the most common cause. This is probably true in those cases in which operation is done with the guillotine. In the new methods by dissection, hemorrhage is always greater when muscular fibers are exposed.

In order to have a clear understanding of the method which I employ, it will be better to follow the plan of the operation as we perform it at the Hebrew Hospital. As to the method itself nothing original is claimed. We simply apply the principle used to control bleeding in all general surgical operations—namely, to catch and tie every vessel showing a tendency to bleed profusely.

The operation performed is essentially that described by Dr. T. Chew Worthington,[7] with some slight modification in the technic. The tonsil is removed by dissection *en masse* in its capsule, with a modified Seiler septum knife, a two-pronged vulsellum being used to pull the gland out of its bed. Patients above 14, and occasionally under that age, are operated on when sitting under local anesthesia. A 0.25 per cent. solution of cocain in 1 to 6,000 adrenalin chlorid solution is injected into the region after the application of a 10 per cent. solution of cocain to the surface. Very little discomfort is complained of by the patient when thus anesthetized. Operations on children, and at times adults who insist on it, are done under ether anesthesia, the patient lying on the back, with the head of the table considerably lowered, so that the blood can not easily enter the larynx; 1 to 6,000 adrenalin solution is also injected before operating. The right tonsil is first removed, the tongue being depressed by an assistant. One or more large gauze sponges held in eight-inch Kelly static forceps and ligated with ordinary No. 2 catgut or clamps are then placed in the fossa and held there gently but firmly. The anesthetist is now directed to anesthetize the patient again fully. This being accomplished, a careful inspection of the fossa is made by holding back the anterior pillar with a pillar hook. Any spurting vessel is caught at once with Jackson's hemoblack silk. While we prefer catgut in most cases because we never hear from it again, it is sometimes easier to use silk. On several occasions, however, in which silk was used in the supratonsillar fossa it became encysted and gave rise to such irritation that we were obliged to pick it out. This does not occur when it is used lower down because it sloughs off during the process of healing.

At times, in spite of much blood pouring down the center of the fossa from above, there is no spurting vessel visible until the supratonsillar fossa is everted by means of a couple of pairs of long dressing forceps. In turning out the fossa we must not be misguided by the cessation of hemorrhage, for often the pressure made during this process is sufficient to close the mouth of the vessel. By lessening somewhat the pressure of the dressing forceps we have often been enabled to find the mouth of the spurting artery. It is from an artery high up in this situation, generally a branch of the descending palatine, that we have most trouble, and there is no doubt in my mind that this artery was responsible for the serious bleeding in Case 1. Ligation of the tonsillar artery has also been found necessary a number of times. Ballenger[8] has found bleeding from this vessel to be more frequent than from any other, whereas Jackson[9] sees the bleeding oftener from the upper vessel, as we likewise maintain. Occasionally it is also necessary to tie a vein or two of the tonsillar plexus.

All bleeding vessels having been controlled, a gauze sponge dusted with Squibb's surgical powder is packed into the fossa to control any oozing, and thus we have our field of operation absolutely free from blood for the removal of the left tonsil.

The second tonsil is removed in the same manner, and after all bleeding is controlled we remove the adenoid vegetations if their removal is called for. Here, too, we control the bleeding with a gauze sponge held firmly in the postnasal space by means of a Kelly clamp. Often no more than one-half to an ounce of blood is lost from the triple operation, and but a small proportion of this comes from the tonsils. Generally speaking, there is more primary bleeding when ether is given than when only local anesthesia is employed.

Many assert that the ligation of bleeding vessels is impossible in the small space afforded us in this region. I do not wish to imply that it is always easy to ligate vessels deep in the fossa; on the contrary, in a small mouth, when the vessel happens to be one the posterior pillar or deep down near the base of the tongue, where the bite of the forceps must necessarily be short, we frequently have to resort to a gauze packer to slip our loop over the end of the clamp. But in most instances we tie the vessels with comparative ease.

It may be argued that the ligature is not always necessary; that torsion will often suffice. Granted that this is true in a number of cases, I believe that by the use of the ligature we not only reduce primary hemorrhage to a minimum, but that we are also secured absolutely from recurrent or secondary bleeding; I have experienced such occurrences only when the vessel was not tied. In one case I was obliged to use ether anesthesia in an adult, several hours after the tonsils had been removed under cocain, in order to catch and tie the spurting artery. This could doubtless have been accomplished with little difficulty during the operation before the effects of the cocain had worn off.

An absolute necessity in catching and ligating the vessels is to have able assistants, as one assistant should evert the pillars while the other sponges and depresses the tongue, leaving both hands of the operator free to catch and tie vessels. This is one of my main reasons for no longer removing tonsils outside of the hospital.

An important point, in my opinion, is that the patient should not be removed from the operating table to his bed until all signs of bleeding have disappeared and the throat is perfectly dry. By so doing we avoid the swallowing of blood by the patient in a semiconscious state, as so frequently happens after the return to bed. Casselberry[10] reports the death of a boy, 3 years of age, after the removal of one tonsil, where the primary bleeding was apparently insignificant and was thought to have ceased; yet a few hours later the child was found in a hopeless condition, the blood having been swallowed. (This patient was not operated on by Dr. Casselberry, but by some other physician whose name was not mentioned.)

It is quite generally recognized that in the presence of hemorrhagic diathesis the clotting capacity of the blood is increased by the calcium salts. In the removal of the posterior turbinal ends, in a number of cases, I have operated on the one side with, and the other side without, the preliminary administration of calcium, and in nearly every case there seemed to be much less bleeding when these salts were given.

Just how great may be the effect of these preparations on tonsillar bleeding it is, of course, difficult to say with certainty, but as it is impossible to tell in what cases hemophilia may exist, it has been my custom for a couple of years past to administer calcium, usually in the form of the lactate, for forty-eight hours prior to every tonsillectomy. One thing is certain: it can do no harm.

Regarding the injection of adrenalin preparation, there is a diversity of opinion. Some operators believe that its use predisposes to secondary bleeding. I recall no instance when the bleeding could be ascribed to the use of this agent, and it seems to me that the advantage offered during the operation, of a less bloody field with our landmarks unobscured, more than compensates for any slight tendency to secondary bleeding thought to follow its use.

This method of controlling bleeding has been used by me for the past ten months in both private and dispensary patients, with the utmost satisfaction. During this time styptics have been given up entirely and the pressure hemostat, formerly often applied, to the great discomfort of the patient, has fallen entirely into disuse.

In conclusion I would say that many obstacles arising at times in the management of some of my cases have been easily overcome through the efficient aid of Dr. Charles Bagley, Jr., and his assistants at the Hebrew Hospital.

1622 Madison Avenue.

ABSTRACT OF DISCUSSION

ON TONSIL SYMPOSIUM (PAPERS BY DRS. ROBERTSON, MAYER, PIERCE, PACKARD, AND COHEN)

Dr. Frank C. Todd, Minneapolis: It is evident that the profession is appreciating the fact that the incomplete operation performed with the tonsillotome has now no place in modern surgery. The removal of the entire tonsil in its capsule leaving intact its bed of muscular tissue and the faucial pillars uninjured gives the best ultimate results. But if the muscle tissue is torn or otherwise materially injured or the pillars are greatly damaged, or portions of the tonsil remain to form adhesive bands between the pillars and to continue the disease process, then the results are not the best that can be secured and may even bring about such cicatricial contraction as to interfere with the normal action of the muscles thereby causing discomfort and disturbance. Yet it is evident that considerable traumatism to these structures may take place and the results be good, even though not ideal. As throat surgeons, however, it is our duty to try to bring about ideal results and so to perfect our technic as to accomplish this end.

While the methods now in vogue differ materially, I can not help but observe that we are coming closer together and experience is bringing us to a method which will be, I believe, more or less universally adopted. A considerable experience has taught me the wisdom of avoiding the use of sharp instruments and particularly scissors and the method which I am using is similar to that described by Dr. Pierce. Dr. Cohen calls attention to the fact that it is not only desirable to stop bleeding on account of the danger to life, but for the sake of losing as little blood as possible, even though that danger does not exist. Dr Cohen quotes some as having claimed that the complete removal of the tonsil in its capsule results in less hemorrhage than following tonsillotomy with the guillotine, while he states that some others claim that the loss of blood is greater. This is undoubtedly due to the difference in the technic of various operators and I believe those who have performed the operation a great deal have worked out a more bloodless method. It will be interesting to secure the testimony of operators some years later when we have determined what may be considered the best method of performing this operation.

In regard to the use of calcium salts to prevent bleeding, I herewith quote an article recently published in The Journal of the American Medical Association, entitled "Pharmacologic Fetishisms" by Wilfred N. Barton, M.D., Washington, D. C. "The salts of calcium are supposed by many physicians—perhaps a majority—to increase the coagulability of the blood. As a matter of fact, they have no influence on coagulation time (Robertson, Illman, Duncan). Nor is it quite clear from a pharmacologic standpoint why they should ever have been expected to do so. Almost all of the calcium taken internally is passed through the bowel unchanged, owing to its extreme insolubility and impermeability. Then, too, it should be remembered that there is almost never any deficiency of calcium in the adult tissues. Treating with calcium internal hemorrhages in which the coagulability of blood is not reduced seems the height of folly. The calcium ion is useless in therapeutics."

Recently it has been called to my attention that the formation of a fibrous clot could be stimulated effectively by applying gelatine and I am now using it for that purpose in the nose as well as the throat. It seems to be effective but I do not feel that my experience is as yet of sufficient value to present the results at this time. One point which I wish especially to emphasize, however, is that of the position of the patient during general anesthesia. To do this operation properly and quickly a good view of the field of operation is required. The positions usually utilized, with which you are familiar, do not afford so good a view as the one which I here advocate, nor have they several advantages which will become evident to you on using this position. This I have learned not alone from my own experience, but from those who have witnessed the operation done in this position. The advantage of the position is not only the good view obtained, which can also be enjoyed by other observers, but there is absolutely no danger of the blood entering the larynx and the blood does not as easily obscure the field of operation. All assistants are out of the way and the first assistant can effectively sponge the blood and hold the tongue depressor.

Dr. Chevalier Jackson, Pittsburg: I think we shall all file away this morning's symposium and the discussion which has followed and study it over carefully. I question very much if there will ever be any one way of doing tonsil operations that will be followed by every one, but if we can break down that Chinese wall we have all put around ourselves with regard to the tonsil operation we can learn much. I thought I knew how to do the operation but two years ago I went to Fall River and saw Dr. Richards doing the work and I went home a wiser man. I found that I had not been getting the tonsils out completely. I was surprised when I found how easily one could determine by feeling in the fossa whether he had cleaned it out. When my former patients return now I take out the rest of the tonsils. One patient came back and I looked in the throat and said, "Why, this is one of the most

---

10. Chicago Med. Recorder, 1893, iv, 1.

beautiful results from the tonsil operations I have ever had." She said "Yes, after Dr. Dickinson fixed it up; he operated two months ago." I began to find out then how Dickinson did it and found that he had a good many good points in technic. We can all learn if we are willing. Every one who has seen Dr. Pierce operate knows the skilful manner in which he handles instruments. The snare he has shown is one of the best I have seen. I can heartily endorse Dr. Cohen's paper. There is no reason why we should use ice for the arrest of tonsillar hemorrhage when we know that we can control it in a surgical manner. I think ligation is at times necessary, though for the smaller vessels torsion is sufficient. It is difficult of course; every thing worth doing is difficult.

In regard to Dr. Pierce's remark as to the uniqueness of my experience in ligation of the carotid, I have been also called to task by St. Clair Thompson in the same way. My position was unique for the reason that as consultant I saw these cases after everything else had been tried and the patient was moribund. I ligated the external carotid in a case in which previously caustics had been used and when the slough began to separate there was oozing again and had the carotid not been tied the patient would have bled to death. Changes in the blood in typhoid fever, diphtheria, erysipelas and other diseases may bring about a temporary condition similar to hemophilia.

As to instruments, we all have our own, of course, and we work with them until to us they are the best.

Dr. F. Gurney Stubbs, Chicago: I think the conclusions we will all draw from this symposium on the tonsils is that laryngology is advancing. One of the chief criticisms that has been levelled at the laryngologist is that he is somewhat provincial: that he is inclined to shut himself up in his own field ignoring the general principles of medicine and surgery. This has led the laryngologist into many errors and it is a sad commentary that at this late day, before a section on laryngology we should have to have called to our attention such a simple surgical procedure as picking up an artery with the clamp if it is bleeding. Probably the reason the tonsil operation has been brought into such bad repute is that every Tom, Dick and Harry in the medical profession has felt that the tonsillotome is all that is necessary for this operation. The papers which have been read to-day thoroughly cover the ground. It remains for each of us to work out his own technic.

We can not get away from the paper on anatomy; that is fixed. Of course, we may have an anomaly in which an artery is not where we expect it to be, but that is extremely rare. In considering the anatomy we must bear in mind that the source of disease, which is one of the indications for operation, is in the crypts and those of us who have for a number of years been shelling out the tonsil in its capsule, with the side toward the muscular tissue smooth and shiny, have been able to put a blunt probe down in the crypts and find that the bottom of these crypts is nothing more or less than this thin capsule. That is why when a tonsillotome is used and half the gland cut off the crypts go on with the disease just the same as before the operation. All that has been accomplished is to make more room in the throat. That important factor was not lost sight of in the indictions for enucleating tonsils.

As to the pathology of the tonsil, and its function, the hypothesis of Dr. Robertson appeals to me as most rational, especially as to the function of the tonsil being past at the sixth or eighth year, and if not previously inflamed tends to atrophy, the same as the adenoid.

As Dr. Jackson has just said, each one of us will probably work out a technic which varies a little from the other man's and it all depends on how familiar we become with that technic and how dextrous. Personally in the last five years I have been removing the tonsil *en masse* in its capsule. We have a body to enucleate which is held in position by no ligments; it simply rests between the faucial pillars held there by a reflexion of the mucous menbrane of the throat over it. Consequently by taking a knife, it doesn't matter what kind, we can easily cut through the mucous membrane and with forceps draw the tonsil well toward the median line in the throat and as soon as we have done that we see that it is attached only by loose connective tissue. Then with blunt dissection you go around it until you get over the line of greatest circumference. From then on it is a question of how to proceed. Some keep on using the knife claiming that when you are so far there is no use discarding the knife for another instrument. Personally I use a snare at this stage and with one contraction of the hand it shells the gland out very quickly. But, of course, that is a matter of preference. The whole operation of removing a tonsil should not take more than two or three minutes.

The question of bleeding then confronts us. In the last five or six years I have never encountered a spurting artery which necessitated a ligature. I think, however, that we should confront the matter as a surgeon would in other conditions. When the tonsil is enucleated in the manner I have described it is easy for you to see the blood vessels of any size that are cut and they are in loose connective tissue which allows them to contract readily. For a second after the removal of the tonsil there may be a rush of blood but as a rule the snare (and that is why I prefer it) crushes the ends of these vessels. As soon as the tonsil is out I take a piece of gauze in artery forceps and hold it in the fossa for a minute and then remove it. If there should be a spurting vessel, catch it up and treat it surgically.

Dr. W. E. Casselberry, Chicago: To secure data bearing on the superiority of results in tonsillectomy, the degree of safety of ether anesthesia for this operation in children and the readiest means of controlling hemorrhage, I have collected my records of 610 cases of patients operated on in private practice which for comparison of results may be divided as follows: (1) Tonsillotomy by the older methods embracing about 40 per cent. with ultimate recurrence of symptoms in one out of five cases; (2) tonsillectomy, not quite complete, in 20 per cent. with few actual recurrences but with many minor complaints from retention of secretions in the few follicles which escaped removal; (3) modern total tonsillectomy, in 40 per cent., with practical freedom from recurrence, in all cases.

Total tonsillectomy is an ordeal through which few adults are able to sit quietly for both tonsils at one time, and as the after-soreness is considerable, an interval of a week between the two is my customary recommendation excepting, of course, when a general anesthetic is given which is always necessary in young children and sometimes in adults to insure the quietude which this operation demands. When done in two sittings, it is reckoned statistically as one operation; 245 cases, nearly all of double tonsillectomy and adenectomy, most of the patients children under 14 years of age have been satisfactorily operated on under complete ether anesthesia without any fatality or other accident excepting threatened respiratory syncope twice which yielded promptly to artificial respiration, and without any subsequent pneumonia or nephritis or any permanent detriment. Midway during the preliminary etherization the throat is sprayed sparingly with a 2 per cent. cocain solution with adrenalin 1 to 2,000, an expedient which accounts for a more satisfactory quietude of the throat with avoidance of delays than is commonly credited to ether. Safety is likewise promoted by a special position of the patient which, while guarding against aspiration of blood, expedites the operating by diminishing the delays caused by bleeding. The right abdominal position which I now use throughout for the heavier patients and in part for all patients, differs from the usual lateral position in that the patient lies, not strictly on the side, but on the abdomen and antero-lateral surface of the chest and shoulder, the right arm being drawn from below backward across the table, which prevents him from rolling off. The face is first directed upward for convenience in removing the right tonsil but at the first free flow of blood the face is rotated downward, which I call the bleeding position, in which as bleeding lessens without waiting for it to stop, one can proceed unembarrassed by the blood flow, to enucleate the left tonsil, provided the operator kneels to direct a good headlight from below upward into the throat. However for smaller children who can be turned quickly and neatly I still prefer the dorsal position with head and shoulders raised, for the first tonsil, turning at the critical moment to the bleeding position for the second tonsil and returning again to the dorsal position for the adenoid.

Hemorrhages requiring supplementary means of control, in children, have been less than one per cent., whereas in adults all methods represented, none proving exempt, they have been 8 per cent., or if stated in terms of single adult tonsils 10 to 25, the ratio figuring the same since the use of adrenalin as before it, and the same for tonsillectomy as for tonsillotomy; but the cleanness of the socket after total enucleation renders it easier to find a bleeding vessel. These hemorrhages were all arterial and continued from 1 to 10 hours, showing no tendency to stop till controlled by the following means: In 8 cases by galvanocauterization; in 1 case by actual cauterization; in 1 case by solid silver nitrate cauterization; in 3 cases by hemostatic forceps; in 3 cases by Mikulicz' compressor; in 1 case by digital compression.

Dr. C. F. Welty, San Francisco: All tonsillar hemorrhage comes from remaining tonsil tissue. To describe just how this comes about, and why it is so I will have to describe the technic of the way I operate. I have stopped doing cocain operations entirely. The patient is sent to the hospital the night before, the bowels emptied and no breakfast allowed in the morning. A half hour before operation a ¼ grain morphin with a 1/150 atropin is given hypodermically; children in proportion, governed by the weight of the patient, and no morphin given to children under four years of age. The patient is placed on the back; primary anesthesia of nitrous oxid is given until they are completely under, and then ether until the patient ceases to struggle or the irritation is overcome; then the mouth gag is applied and the head drawn toward the right, the operator sitting on a chair. I have been using Dr. Rupert's cannula in the mouth. At this stage the throat is apt to be filled by mucus which is cleared away and a 1 to 1,000 solution of adrenalin is injected into the mucous membrane around the tonsil, about ½ dram. Then with any kind of a knife the mucous membrane is severed just where it attaches to the tonsil; and this is a very important step. My assistant holds the tongue and that is all; I take care of the hemorrhage myself. I use one anatomic forceps and one nasal forceps with an acute angle. I can change my hold of the tonsil with this very easily without causing hemorrhage. This incision through the mucous membrane is all the cutting that is done. Then I introduce the anatomic forceps and sweep it around and generally find that with a single sweep the tonsil is out in the throat. Sometimes it takes longer and sometimes the adhesions must be cut. Then the snare is put on and the operation finished. There may be a rush of blood, when a sponge is put in and held there for a minute or so, being changed as soon as it is saturated with blood, and being held with considerable pressure. If the bleeding does not stop in a short time I look for the bleeding vessel and grasp it with the forceps, allowing them to remain on for a few seconds and then taking them off. If it continues to bleed I suture the pillars at once. I never allow a patient to leave the table while bleeding. I have 250 such cases to report, with one severe bleeding, and in that case the tonsil was not sufficiently removed.

Dr. George L. Richards, Fall River, Mass.: There are two types of these tonsils—the large ones which stand out in the throat, and the smaller submerged ones in which the capsule has considerable fibrous tissue running down into the tonsil. In order to get any tonsil out completely you must do the operation extracapsularly. Dr. Jackson has kindly referred to me in connection with the finger nail operation; I did not originate it. There is a point where the line of cleavage between the capsule and fossa allows the finger nail to go through. It has one advantage over the blunt instrument and that is that you have the sense of touch, and you can get up into the supratonsillar fossa and get the velar lobe and bring it down into the throat. As soon as the tonsil is out in the throat I apply the forceps and then detach with the tonsillotome or snare. You can operate with any type of instrument with which you are familiar, but the main thing is to do the operation extracapsularly.

The question of tonsillotomy or tonsillectomy is not yet settled. One-third of the operators are still doing tonsillotomy, thinking the complete unnecessary. They have not studied the literature of rheumatism and kindred infections which have their portal of entry in the tonsils or they would change their minds. I agree with Dr. Welty as to hemorrhage occurring because of incomplete operation, though this is by no means always the case. Robertson showed us at the New Orleans session how to get the entire tonsil out and showed then that hemorrhage was sometimes due to incomplete operation. But the majority of cases reported in the literature do not seem to have been due to that cause. The six cases reported by Heuking came from injury to the pillars. It may be that this is sometimes the case, and it is as apt to be due to the tonsillotomy as to the tonsillectomy operation. It is easy to cut one of the pillars longitudinally and that is the worst bleeding to stop. One advantage of the finger method is that bleeding from this point is less apt to occur.

Dr. J. F. Barnhill, Indianapolis: I wish to subscribe to most that has been said concerning thorough work in tonsil dissection, but I do not believe the time has yet arrived when we should say that all tonsils should be removed by tonsillectomy. It has been said over and over again that we do not know what the function of the tonsil is, and until we do know that it has no function we should not in every case remove it *in toto*. In the kind of tonsil that Dr. Mayer has spoken of as the projecting tonsil it is not always necessary to remove it by dissection. I wish to defend local anesthesia for tonsil dissection. In the great majority of cases it is not necessary to subject the adult patient to general anesthesia for the purpose of total enucleation of the tonsils. With our modern means, and with modern remedies at hand, we may with local anesthesia now state to the patient that we can dissect out his tonsils without the least pain. The tonsils may immediately be dissected loose and removed together with their capsules. I do not have any one hold the tongue except the patient himself. There is a good psychic influence in this aside from the benefit you have of having every one out of the way. They may say they can not hold his tongue down, but you tell them that all others have done so and they will succeed nearly always better than any assistant could.

In regard to hemorrhage, of course everyone should be prepared to meet the emergency. I do not believe that it is always necessary to tie these vessels. Many of the vessels that spurt only slightly will check quickly and we do not hear from them again; nevertheless, I agree with Dr. Cohen that we should be surgeons and therefore prepared to do the work surgically when it is necessary.

Dr. Mark D. Stevenson, Akron, Ohio: The surgery of the tonsillar fossa, outside of the removal of mechanical obstruction, is primarily for the removal of retention spaces. There is little benefit obtained, either locally or to the general economy, if spaces remain after tonsillectomy due to pouch formation from scar contraction, or too free granulation or folds in the pillars, the harm depending on the amount of retention. To prevent pouch formation it is usually best to sacrifice the plica triangularis and sometimes a part of a very large overhanging anterior pillar. I also use a high table but I sit on a low stool. The patient lies on his side with his upper shoulder resting against a sidepiece which is placed on the table, and which comes to within a short distance of the head of the table. The patient's head is lower than the neck, and his face points downward and toward the operator so that blood or vomited matter readily runs out of the mouth. I think that in Dr. Todd's position a port of the already too small breathing space would be filled with blood. After complete enucleation of the tonsil, I find it very difficult and sometimes impossible to seize bleeding vessels with an ordinary hemostatic forceps, so I have had a forceps made pivoted with small sharp teeth on the end which readily seize the vessels in the moving pharyngeal muscles. It is slightly larger a short distance from the end than at the end, making it easier to slip the ligature down to the tissues in ligating a vessel. I do not find it difficult to ligate vessels during the operation but very difficult afterward when the patient is nervous and weak. One-half hour before operating a small dose of bromids is given to quiet patients when a local anesthetic is to be used. After removing a tonsil under general anesthesia steady pressure of gauze in the fossa usually quickly stops all bleeding. I prefer to use a knife alone or a knife and snare under general anesthesia, but under local anesthesia when it is important not to pull the tonsil which causes pain, especially that complained of in the Eustachian region, I much prefer the scissors and use three different shapes, one curved on the flat, another on the edge, and a third especially bent to cut free the base of the tonsil which usually lies considerably below the level of the tongue, and is difficult to cut with ordinary scissors. Under a general anesthetic the finger is one of the most useful instruments but I never employ it under local anesthesia. In dissecting the pillars free, the finger also makes a useful tongue depressor, and in addition, backward pressure can sometimes be made against the tonsil so that the knife does not draw it far from its fossa which causes after pain toward the ear.

Dr. Percy Fridenberg, New York City: As to tonsillar hemorrhage, ligation of the bleeding vessel is a counsel of perfection. Undoubtedly the surgical procedure described is the best, but in some cases we can not apply that procedure as we would desire; for instance, if we are called to see a case in which bleeding has been going on for some time it is almost impossible to find the vessels and catch them up and ligate them. In a case of severe tonsillar hemorrhage, as in epistaxis, the extreme restlessness and fear, the anxiety of the patient, often attended with shock and collapse or attacks of syncope, may make it impossible to get near the bleeding point until the action of the heart has been depressed, preferably by narcotic. This alone, by quieting the patient will sometimes stop the bleeding, and may be the only way of preparing for the surgical procedure which has been advised. When you are called in haste to such a case, and see blood everywhere: the patient spitting and coughing blood, the surrounding attendants "sweating blood," it is no easy matter to ligate a torn tonsillar vessel. In these instances we have to have recourse to measures which are not all we would wish, and among these measures I would mention a good strong hypodermic of morphin and digital compression.

Dr. F. E. V. Shore, Des Moines, Iowa: If we are to be so perfect in our surgical technic, and do these operations as surgeons would, it is surprising to me that one would discard the knife in a portion of the operation and use the snare to complete the work. I should as soon expect the general surgeon to use the snare in removing the appendix or for amputating a limb. It is certainly non-surgical and when the operation can be finished just as well without danger without changing the instrument, I can not see why we should not use the knife. Personally I have always used a sharp knife with a round point as sharp as it is possible to get it. It doesn't necessarily follow that I use the sharp edge at every step of the operation. As soon as I have divided the membrane, I dissect it up from the tonsil, separating the loose tissue until the tonsil is free. I do not believe it is a surgical procedure to run the finger down the throat. It is certainly not as aseptic as to use the knife which can be done just as well. I always precede the operation with the use of adrenalin.

There is one other point and that is as to the anesthetic. I must confess that I am not in harmony with the majority of the members as to the preferable anesthetic. I have operated in about the same number of cases that Dr. Casselberry mentioned, have used chloroform and in but two cases have I had difficulty. In one of these instead of using adrenalin I used adrin which I understand is twice as strong as adrenalin. In the other case, I used 10 per cent. solution of cocain applied to the throat. Both patients were children and there was temporary collapse. In a large number of cases, the status lymphaticus spoken of is really a status anestheticus. The anesthetist is at fault. Chloroform is safe if the anesthetist is familiar with his work. I never have hemorrhage any more. The patient must be prepared as for general operation, work done by preference in early morning before the patient has partaken of food or liquids. When the chloroform is administered, the patient should be in recumbent position with same after-care. I had some very severe hemorrhages in my early operations but have had none since adopting the routine method of ligation of the spurting vessels and in adults stitching the pillars. I remove the stitches in twenty-four hours.

Dr. O. Tydings, Chicago: Beginning this work some years ago, I first used the guillotine, then the blunt pointed curved bistoury, and later the cautery, for the entire removal of the tonsil. In 1902 I began the use of the knife and snare. I would separate the pillars and free the tonsil from adhesion with sharp knife occasionally using a blunt dissector until I could engage the tonsil in the loop of the snare. I spoke of this method five years ago and was reminded that the blunt dissector had been used 1,000 years before. I still have occasional use of my blunt dissector. I think Dr. Welty has struck the keynote as to the cause of hemorrhage, as our experience at the Chicago Eye, Ear, Nose and Throat Hospital shows. Dr. Stubbs, who spoke kindly of my knife, and I do two-thirds of the throat work at that institution; he reports no hemorrhages. I have had six cases of hemorrhage reported to me in the past seven years, three of which I saw. I did nothing in either case as the hemorrhage had been arrested before my arrival. There are many means by which we can control hemorrhage; one is by producing an artificial hyperemia, by constricting the limbs, by lowering blood pressure with an injection of morphin or anything to divert the current of blood from the parts. That all are not so easily arrested is evidenced by the following: A few weeks ago I was called up by a gentleman to know what to do for a case of hemorrhage. I told him what I would do but he did not heed the advice as he had succeeded without it. When a man leaves part of the tonsil and goes back after it with a punch to remove it, he is not doing clean surgical work. The cases of hemorrhages that I have been called on to treat have been other physicians' patients in whom there had been a partial removal of the tonsil. I may run across one of these severe bleeders some day, but I haven't yet; but I certainly should not feel alarmed, if I did, if I had an ordinary pair of forceps in my hand.

Dr. Oscar Wilkinson, Washington, exhibited a curved needle by which, after packing the fossæ with gauze, one could stitch the two pillars together. By putting in two or three stitches over the packed cavity one will not have any trouble in controlling the hemorrhage.

Dr. W. W. Carter, New York City: The snare is the method I usually employ in removing the tonsils. I was surprised to hear from Dr. Wright a few days ago that probably in nine-tenths of the tonsils removed by the snare there were found to be, on the outside of the tonsil so removed, striated muscular fibers. I believe this is due to two things: first, failure to follow the line of cleavage between the tonsil and fossa in separating the tonsil prior to applying the snare; second, to pulling the muscular tissue into the snare loop before bringing it home. I have seen within the last six months three cases in which the proper action of the posterior pillars has been interfered with by the removal of a portion of the muscular tissue by the snare. There was regurgitation of liquids through the nose. I wish to warn, therefore, against the use of the snare when the tonsil has not been properly liberated from the surrounding tissue, and from too great traction being made on the tonsil before bringing the snare home.

As to the use of the hemostat, I believe that it has its use, but that it is one of emergency, and should be limited to the time it takes to get hold of proper forceps, needles and sutures for stopping the hemorrhage in a strictly surgical manner. The amount of traumatism following the use of the tonsillar hemostat has been observed by me on several occasions. I saw a case recently in which the cellulitis following was sufficient, I am afraid, to cause the death of the patient. The proper method for stopping hemorrhage is to ligate the bleeding vessel, and this principle should be adhered to as strictly in throat surgery as in other parts of the body.

Dr. Joseph White, Richmond, Va.: I have operated for the removal of tonsils considerably more than one thousand times and never had a fatality and have only seen twice what I considered a very dangerous hemorrhage. In one case, I had to ligate the external carotid artery; in the other digital compression for six hours stopped the bleeding. I have not met with any other annoying or dangerous hemorrhage, and if you want a perfectly dry field you have nothing to do but make digital compression on the carotid against the spinal column. Most of the cases of bad bleeding are in adults and not in children, and compression on the carotid in this way will give you a dry field. When you release the pressure you can see the bleeding point and grasp it with a hemostat and the best one I have used for this purpose is Jackson's. Most cases of bleeding have been associated with nephritis, and the urine should be examined before operation in every case.

Dr. D. J. McDonald, New York City: I wish to speak of the question of backward children. As one looks at the matter of the discussion here to-day and notes the advances being made in this new field we must come to the conclusion that whatever method we employ we should be perfect in our operation. We know that thousands of dollars are lost to the city of New York, where there are eight hundred thousand children, because of these conditions. So that it is a matter of great importance to the community at large it behooves us to stir ourselves in order to better these conditions and save the community from excessive taxation. I have followed out the line of work of Dr. Richards, which can be done without a great surgical armamentarium. There are, of course, dangers connected with every operation. We could show that at least 40 per cent. of the troubles of childhood are due to these conditions. Let us do the work thoroughly, no matter by what method, and save the state, the nation and the child.

Dr. N. L. Wilson, Elizabeth, N. J.: I believe that any tonsil which needs to be removed should be thoroughly removed by a tonsillectomy. I have had more pain, more infection and more bleeding from tonsillectomy, but I believe that if the work is to be done at all it should be done in this thorough manner. I do not believe in giving morphin as it abolishes the reflexes which are so important. As to adrenalin, the majority of physicians I find use it too strong. It should not be used in a strength of more than 1 to 7,000 or 1 to 10,000. Just as good a hemostatic effect is obtained with the weaker solution. The question of light has been to me a very serious one. At the present time I am having one constructed for me on the plan of the Todd transilluminator. Ether is my choice as a general anesthetic, cocain and adrenalin for local anesthesia. The nurse is always instructed to watch the patient, and if she observes frequent swallowing to notify the doctor to examine the throat for bleeding.

Dr. Otto Glogau, New York City: In the April number of *American Medicine* I called attention to the importance of nasal examination in these cases. This is often neglected. It is necessary, especially for this work of education, to tell the school inspectors to pay more attention to the nasal condition of these children, as the correction of some primary nasal defect will avoid unnecessary removal of lymphoid tissue. Tonsillectomy may be indicated in some cases in which the patient or the parents are tuberculous or rheumatic. We do not yet know perfectly the function of the tonsils. Formerly the surgeons removed the whole thyroid but they do not now. When it is known that after the age of 12 or 14 years the tissue shrinks up why should we remove it thoroughly if the only symptoms are the interference with breathing? In most cases a well-performed tonsillotomy will give enough relief. The chiefs themselves in the dispensaries do not do this work and it may be dangerous if the young men should perform tonsillectomies. Besides a tonsillotomy, if done *lege artis*, takes a very long time and can only be performed under general anesthesia. Therefore at least in dispensary work tonsillotomy will be the only available method.

Dr. C. M. Robertson, Chicago: A great deal of hemorrhage is from the palatine and tonsillar arteries which are given off from the external maxillary, sometimes very close to the external carotid. There is likely to be a hemorrhage necessitating ligature, because the vessel is cut so short that the blood clot is forced out of the vessel by the pressure of the blood current.

Dr. Emil Mayer, New York City: In regard to my own portion of the subject I tried to emphasize the fact that not every tonsil that comes to us is grist for our mill. A child who does not present symptoms of obstructed breathing and has not had any previously existing tonsillar disease should be left alone until such time as the tonsils have had a chance to atrophy or until they become enlarged sufficiently to justify an operation. I was pleased to have Dr. Pierce make a suggestion which I shall surely follow—that of seizing the uvula with forceps and holding it out of the way to prevent its being engaged in the snare.

That anesthesia should never be given in a physician's office is absolute and positive; death after death has been reported from following this procedure. Chloroform is dangerous. These operations are done for the promotion of the welfare of these children and are not operations of necessity or emergency and, therefore, it is the more tragic if anything happens and we should be very cautious. In the adult both tonsils should not be removed at the same time.

In regard to the use of instruments: We have had instruments for the separation of the pillar; sharp instruments have been shown, and blunt ones, and we have seen some of the fingers: now I have something to show you which is in between these. I have taken the curved tonsil separator and had the edges serrated; with this the tonsil is readily enucleated. As to why we discard the knife at the final stage, that is a perfectly simple thing. We discard it in the lower portion because we have almost enucleated the tonsil and we come to the point of greatest danger and the snare enables us to complete the operation without danger. While we do not have hemorrhage we have a bloody surface and I would like Dr. Cohen to tell us how he ties these vessels. I think it is not so simple as has been expressed. As to the statement that the chiefs of clinic allow the younger assistants to do tonsillectomies, if the gentleman will visit my own clinic he will find that this is not so. My competent assistants do that kind of work and to each man is assigned a patient to be operated on and there is a check on him in the punching of the card to show who has done the operation. The junior is not allowed to do it until he has had long experience and has shown by his ability to do other things his dexterity in doing the more difficult operations; it is the last thing he is given to do.

Dr. Norval H. Pierce, Chicago: Dr. Mayer has expressed my ideas so much better than I could, that there is not much left for me to say. Regarding tonsillectomy versus tonsillotomy, Chicago I believe has been the battle ground. We have had some very warm discussions there and I was, and still am, a disbeliever in the removal of the tonsils as at one time advocated by some of my colleagues, For instance, in the early days of the work a gentleman showed me some specimens of tonsils encased in the lateral wall of the pharynx and of which he was very proud but which showed that he did not do a tonsillectomy, but a pharyngotomy; he took out pharyngeal tissue with the tonsil and not a little of it, either. I was called to see a patient after such a pharyngotomy. The patient was suffering with profound sepsis from which he recovered after a long illness and to this day he has a torticollis. It is very important to keep within a safe distance of the muscular tissue surrounding the tonsils and I think the snare does that better than any other instrument or method, not excepting dissection by the classical finger, described most beautifully by no less a gentleman than our esteemed colleague Celsus, who lived, as you know, some time before the present advocates of that method.

Dr. Lee Cohen, Baltimore: I should like to correct a seemingly prevalent, false impression that I have had an unusual number of severe bleedings. In ten years, I have had about eight cases, which I considered more or less troublesome. Perhaps some other operator would not have looked on these as very severe. Only in the two cases reported have I had any great difficulty in controlling the hemorrhage. The ligature is used not only to guard against serious bleeding but to reduce the loss of blood to the minimum, so that in frail children, convalescence may be hastened. As to the difficulty in seeing the vessels in case of profuse hemorrhage. This can always be satisfactorily overcome by packing the fossa with from two to four gauze sponges held in Kelly clamps, the pressure from which stops the bleeding for the time being. By removing one sponge at a time, beginning from below, we are enabled to inspect the fossa in sections, and thus the bleeding point can be seen with ease.

The method of tying is as follows: The hemostat being held by an assistant, a loose single loop of No. 2 catgut is tied around the shank of the forceps and slipped down to the lower end by means of the left index finger, while the other end of the catgut is held in the right hand, no part of which need enter the patients mouth. By bending the forceps over, or as expressed by Dr. Finney of Baltimore, by "rocking" it, the loop is pushed over the end of the hemostat, where it is held by the index finger, while the right hand draws the knot tightly. The clamp is now removed and the tying completed. With catgut, three loops should be used. Though incomplete removal may be the cause of severe hemorrhage, I can not agree with Dr. Welty, that it is the sole cause. In both severe hemorrhages reported by me, the tonsils were removed completely, with capsule intact, leaving a clean, smooth fossa. As to the removal of each tonsil separately, as suggested by Dr. Mayer, this may be advisable when a great deal of blood is lost from one side. When bleeding from the one is completely controlled by the ligature, however, before the other is excised, I can see no need of twice incapacitating the patient. I always remove both at one sitting.

There are two minor causes, which have appealed to me: One is foul breath when nothing but decomposing tonsillar secretion can be found to account for it. Another is pain referred to the ear, but in reality due to secretion pent up in the supratonsillar fossa. Tonsillectomy promptly relieves both conditions.

TRIFACIAL NEURALGIA *

FREDERIC V. HUSSEY, M.D.
PROVIDENCE, R. I.

One has only to glance over the literature covering the subject of trifacial neuralgia to realize the state of mind in which the medical profession has been in regard to the pathology and treatment of that most painful affection. It is well known that the more uncertainty there is as to the etiology and pathology of a disease the more varied is the treatment and the less uniform are the results. Rarely do we see anything approaching specific treatment of a disease unless the inciting cause and the resulting reaction are known.

The suffering occasioned by trifacial neuralgia has been such as to have excited for years the interest of physicians in the endeavor to find some means of permanent relief. The treatment of the disease has varied according as the ideas of the cause and pathology have varied, and it does not seem probable that the treatment will ever be uniform until a definite knowledge of such pathology is established. It is not the purpose of this paper to present any new information on the subject as the result of original research, but rather to endeavor, if possible, to arrive at some definite conclusions on the nature of trifacial neuralgia from an examination of the already existing literature on the subject.

For a long time it has been known that certain constitutional states of the body can produce a neuralgia of the trigeminal nerve. This is occasionally seen in such diseases as diabetes mellitus, malaria, syphilis, exhaustion, chronic nephritis, rheumatism, gout, lead poisoning, *et cetera*. As long ago as 1891 Dana[1] called attention to the fact that patients suffering from trifacial neuralgia very frequently have associated with that condition one of general arteriosclerosis. This led him to believe that arteriosclerosis was the chief cause of neuralgia. This view has been supported at times by others, notably by Putnam,[2] who published in 1891 ten cases in which he found an endarteritis and a general fibrosis; and by Horsley,[3] who had already advanced the same idea in 1887. Later, in 1897, the same surgeon, in discussing the pathology of trigeminal neuralgia, stated that he had not found any more degenerative changes than could be accounted for by the age, condition and habits of the patients.

Cushing[4] admits that arteriosclerosis is a persistent condition, but asserts that it follows the neuralgia and is a result of the pain. In support of this view, he cites a case in which, before operation, the blood pressure averaged 190 mm., rising to 200 mm. during the paroxysms. Since operation the average pressure has been 140 mm. The condition of heightened blood pressure is brought about, he thinks, by constantly recurring afferent impulses, which, like hard work, lead to changes in the vessels. Undoubtedly the condition of arteriosclerosis can produce trifacial neuralgia, and in these cases the use of the vasodilators to the proper degree will relieve the pain. It is easily conceivable, also, that the constantly recurring paroxysms of pain can aggravate an already existing arteriosclerosis, so that after operation an improvement will be seen in the blood pressure.

Tumors of the base of the brain, of the skull and of the Gasserian ganglion itself, may cause a neuralgia of the fifth nerve, as can also irritative conditions about the nose and mouth. Porcher,[5] in 1903, reported six cases in which the neuralgia was due to localized inflammation in the nose, antrum of Highmore or teeth. In two of the six cases, the Gasserian ganglion had already been removed by well-known surgeons, with a recurrence of the pain. Both patients were cured by proper drainage of the antrum of Highmore.

In 1905, Snow[6] reported 20 cases in which the neuralgia was due to intranasal pressure or a collection of pus within some of the accessory sinuses. He said he had seen "many cases of the acute form of tic douloureux accompany a cold with sinus accumulation and pass away with abatement of the inflammation or proper drainage of the nose." Somers,[7] in a paper in 1906, mentions the nose as a frequent and often unrecognized cause, and states that hypertrophy of the turbines, especially the middle, not infrequently produces both supraorbital and infraorbital neuralgia. He also calls attention to inflammation of the frontal, ethmoidal, sphenoidal sinuses and of the antrum of Highmore, as causes of trifacial neuralgia.

In the mouth, impacted third molars, carious teeth, pulp nodules found in the pulp chamber, and decayed roots entering the antrum of Highmore and producing antrum disease, frequently bring about a neuralgia of the fifth nerve. It is also well known that mere exposure to cold or damp weather is sufficient to start up attacks in some patients.

The type of lesion induced by the foregoing causes, which are irritative in character, is probably either a degenerative one or a peripheral neuritis which may be ascending in character, and may secondarily involve the Gasserian ganglion. But the number of cases of tic douloureux coming under this division is small and there remains by far the greater majority in which no constitutional or local irritative cause can be found. This gives some grounds for thinking there may be two types of neuralgia; one in which the lesion consists primarily of a neuritis of the peripheral branches which may be ascending in character, and another in which the primary lesion appears in the Gasserian ganglion.

The first group might be said to include the minor neuralgias in which the pain is not so intense, or the attacks so paroxysmal. The second group includes the major neuralgias in which the lesion is primarily central. These neuralgias are characterized by their paroxysms which tend to recur more frequently and to become progressively worse and by the associated facial tic.

Is there a definite pathology to be found in these cases of major neuralgia?

Rose[8] found a thickening of the interstitial connective tissues of the ganglion, and an irregularity in the form of the ganglionic cells. On this basis he regards the disease as a chronic inflammation resulting in contraction and compression of the nerve cells. Horsley,[9] in 1897, said he had not found more degenerative changes in ganglia than could be accounted for by the age, condition and habits of the patients. Krause,[10] in 1896, found degeneration of the ganglionic cells and nerve fibers, but no sclerosis or endarteritis.

In 1898 Spiller[11] gives the following as a result of the examination of seven ganglia removed by Keen:

> The medullary substance of the nerve fibers within the ganglion and its branches is much swollen, atrophied or entirely gone, depending on the intensity of the disease. The axis cylinders similarly are markedly degenerated or entirely destroyed. The vessels are very distinctly sclerotic, in some the lumen being entirely obliterated. There is also an increase in the connective tissue of the ganglion.

Two years later Barker,[12] in reporting the condition of two ganglia after removal, said that there were scarcely any normal-appearing cells; some of the nuclei were swollen and concentric bodies were present.

Schwab,[13] in 1903, reported the microscopic findings in four ganglia, two of which were removed before any peripheral operation had been done. The condition found in these four ganglia was the same as was found in two others reported the year preceding. He said:

> In all the ganglia a certain number of distinctly abnormal cells have been found. The number is too large to be accounted for by the accidental effect of faulty technic or through any hardening or staining processes. The cell changes have been found mostly in the peripheral portions of the ganglia, and in those cells which are characterized by staining deeply, by elongated outline and by their small volume, as compared to the cells which lie in the deeper portions of the ganglia. The changes found in the cells vary all the way from a slight degree of chromolysis to profound changes of total cell disintegration and nuclear migration. In three of the six ganglia perinuclear pigmentation was present in large numbers of the cells. In one of the ganglia a sclerosis of the periganglionic tissue with excessive connective tissue formation around and between the cells was found, which was so pronounced that its pathologic significance is unquestioned. In some of the ganglia neuritic changes were found in the peripheral branches, but only in those cases in which a peripheral operation had previously been done.

Later on Schwab, from twenty cases, concludes that there is a neuritis ascending *from the* terminal branches; that there is an interstitial inflammation of the ganglion, and that there is a central neuralgia affecting the roots at their entrance into the *pons*.

In 1904 Spiller[14] stated that, of 159 ganglia examined, all presented evidences of degeneration. Davis[15] also reported, in 1904, a ganglion examined by him, which showed advanced degeneration. Gordon,[16] two years later, in eight ganglia, "found the blood cells more or less thickened, depending on the age of the patient. The nerve bundles situated in the vicinity of the altered blood vessels always showed distinct degeneration. The duration of the disease has no special bearing on the degree of involvement of the nerves." He concludes as follows:

> The occurrence of degeneration of peripheral nerves is frequent, if not constant in neuralgia. This nerve degeneration is probably a primary one which, as a neuritis, assumes an ascending condition, and secondarily involves the Gasserian ganglia; the blood vessels undoubtedly play a certain rôle in the causation of a degenerative state of the peripheral nerves. It is difficult to draw a sharp distinction between neuritis and neuralgia, as accumulated facts tend to show an anatomic basis for the latter affection.

Cases are on record in which the ganglion removed by operation has showed nothing abnormal on microscopic examination. Caminiti[17] points out that at times cellular changes are present in the ganglion when tic douloureaux has not even existed.

Dana has suggested, I believe, that the pain occurring in women in early years may be in the nature of migraine; but that after a number of years the pain becomes chronic and more definitely located in the divisions. In the beginning, he says, it may be a disorder of the sensory neuron, neither in the *ganglion or in the* peripheral branches, but later certain degenerative changes may develop in the branches. The pain occurring after 40 years of age is due to a definite lesion either in the ganglion or in the branches.

The type of lesion in trifacial neuralgia when present has been either a degenerative one, an inflammatory one, as interstitial neuritis, or a neoplasm. As I understand, Spiller, who perhaps has made as careful a study of the subject as any one living, and whose experience has been extensive, has not yet examined a ganglion which has not showed evidences of abnormality. And yet, in a personal communication to me, he said that he was not ready to state that there was a definite pathologic condition to be found in every case of trigeminal neuralgia. Possibly the consensus of opinion may be summed up in his words:

> I should be unwilling to say that pathologic changes will be found in every case because we must believe that in some instances sufficient time has not been given for severe alteration to develop before the ganglion was removed.

And still, if the lesion is in the ganglion, why will division of the second and third branches of the fifth nerve, as they come off the ganglion within the skull, cure, for the time being at least, the neuralgia occurring in those divisions? In certain cases of recurrence in which Abbe operated a second time, it has been found that the pain has returned with *regeneration* of the nerve trunks. It was this fact which led him, in 1903, to adopt the method of interposing rubber tissue between the cut ends of the nerves to prevent reunion. If the lesion is in the ganglion, why should division of the peripheral branches give relief? Have not the better end-results obtained in complete removal of the Gasserian ganglion been due to the impossibility of regeneration of the nerve fibers? Spiller[14] says:

> Very few ganglia have been entirely removed without relief of pain; indeed, I know of only two cases, and I am skeptical concerning these.

It seems also that we have a great deal to learn about the chemical changes in nerve cells during discharges of nerve impulses. "It seems possible that long after primary irritation has ceased, an abnormal chemical state may remain and excite the pain."[18]

We may divide the treatment of trifacial neuralgia into medical and surgical. In determining which to advise, it is necessary, if possible, to find the cause of the disease. Also the duration and frequency and severity of the attacks must be considered. It has been estimated that nearly 20 per cent. of the cases of trifacial neuralgia are amenable to treatment other than surgical. In view of this fact, it seems advisable first to recommend medical treatment to be given only for a short length of time unless improvement in the symptoms is seen. It is needless to say that in those cases recurring after some peripheral operation, medical treatment is contraindicated.

In the treatment of neuralgia of the fifth nerve by medical means, we should first remove, as far as possible, all predisposing causes, such as anemia, malaria, lead-poisoning, syphilis, etc., giving each condition its appropriate treatment. Occasionally, this alone will be sufficient to correct the neuralgia. If the patient is arteriosclerotic, the vasodilators pushed to the degree of producing a sufficient softening of the pulse may control the pain. In the migrainous type of neuralgia, according to Dana, surgical treatment should never be advised, as the lesion is probably located in the central nervous system. One has only to glance over the long list of drugs recommended for use in trifacial neuralgia to realize the uncertainty attending the use of any one. I shall speak of only one, namely, strychnin, as it seems to be the most reliable. It should be given in large ascending doses once daily subcutaneously. If a favorable response occurs, after the pain has disappeared, the drug should be gradually withdrawn.

In 1903 Zimmern[19] published an article giving the results obtained in eighteen cases treated by galvanism. He applies the constant galvanic current of an intensity of eight to fifteen milliamperes over the affected nerve endings for an hour or more at a time, after having first placed a large flat electrode over the nape of the neck, and a half mask of heavy tin-foil moulded to shape the face. In this way, as the current is distributed, no burning occurs. Of the eighteen cases of severe type treated in this way, Zimmern was successful in every case. The value of this treatment has been subscribed to in this country by Zabriskie and others.

In view of the fact that certain cases have been reported in which the neuralgia has been ascribed to nasal and buccal conditions and has been relieved by the correction of those abnormal conditions, a thorough examination of those cavities should be made. One should not be in a hurry, however, to ascribe the neuralgia to the teeth, for many patients have been martyrs to the cause in the past and have sacrificed all their teeth on one or the other side, without relief to their pain. But, as we do know that a carious tooth, antrum disease, accessory sinus disease or hypertrophied turbinates occasionally produce neuralgia, those conditions, if found to exist, should be corrected in the hope that by so doing we may reach the cause of the trouble.

Experience has shown that by the above means a certain number of cases of neuralgia of the fifth nerve will be arrested, either permanently or for longer or shorter intervals. Medical treatment, however, should be given only a fair trial. If the attacks are very frequent, severe and uncontrollable, one should advise an operation.

The injection treatment of trifacial neuralgia has been practiced with more or less success since Billroth and Neuber first began to use osmic acid in 1884. Many cures were reported as a result of this treatment. In 1900 Schlösser began to use 80 per cent. alcohol instead of the osmic acid. As yet he has not made, I believe, a complete report, but from time to time statements have been made by him and by other surgeons, showing that much is to be expected from the alcohol injections. The object of the treatment is to reach the second and third divisions just at their exits from the foramen rotundum and foramen ovale, respectively. It is not necessary to inject the alcohol directly into the nerve sheaths, but only into the vicinity of the nerve trunks. The operation is not a difficult one to do, and as yet no bad after-effects have been noticed. As a result of the injections, a degenerative reaction is set up in the nerve, the effects of which are only transitory. Anesthesia of one-half of the anterior part of the head from the vertex to the chin is produced, as well as some incomplete paralysis of the masticatory muscles, which usually passes away in a few hours, but which may, according to Ostwalt,[20] last two or three months. The nerve recovers its normal condition, but "the pathologic irritability causing neuralgia disappears for a long time."[21] Ostwalt[20] reported, in 1906, sixty cases of trifacial neuralgia treated by injections of 80 per cent. alcohol; one-third of the patients had recurrences within five months of the time of the first injection. The relapse, as a rule, however, was much less severe and was promptly relieved by other injections. In 1907, Schlösser, at the Medical Congress at Wiesbaden, reported 209 cases in which relief from pain lasted on an average about one year from the time of the injections. Kiliani has reached his hundred-and-eightieth case and states that "his failures are exceedingly few." Patrick[22] published sixteen cases with one failure from supposed inability to reach the nerve. Of the sixteen patients, four have had occasional recurrence of pain, but they refused further treatment.

A permanent cure following a single injection is not, as a rule, to be expected. Recurrences may take place at any time from five months to one year. But Schlösser says that repeated injections delay the recurrences more and more, so that an almost absolute immunity from pain may ultimately be promised these people. It would seem as if the method has been given a thorough enough trial to mark it as a very successful palliative method of treatment.

The history of the operative treatment of trifacial neuralgia has been one of failure, until the intracranial operation was advised and performed in 1890. Since then the results of operation have been steadily growing better. The peripheral operations were a failure in most cases, because of regeneration of the nerve fibers. Still, in those cases in which a peripheral operation is indicated, good results may follow if measures are taken, such as plugging the foranina with silver screws or plugs, to prevent reunion of the ends of the divided and avulsed nerves. Peripheral operations on the third division, for one reason or another, are usually followed by better results than operations on the other two divisions. Frazier[23] says that, if pain is restricted to the distribution of the inferior dental branch of the third division or to the infraorbital branch of the second division, there is no question but that a peripheral operation is the one of choice, because the risk is less from this operation; a certain percentage of patients will recover, and a larger number are given relief, at least for some time One should always, however, resect a considerable portion of the nerve, or remove as much as possible by avulsion and plug the foramen.

When recurrence follows one or more peripheral operations, or when the distribution of the pain becomes more widespread and is no longer limited to one, but is referred to two or all the branches of the ganglion, the period in which the peripheral operation is indicated has passed.

There are many variations in the procedure of surgeons in performing the intracranial operation. Some surgeons, as Abbe,[24] prefer to divide the branches, resect a small portion as they leave the anterior aspect of the ganglion, and then interpose rubber tissue between the cut ends to prevent reunion. Other operators, as Cushing,[4] Krause, Lexner,[25] favor total extirpation of the ganglion; while others, as Frazier and Kocher, prefer division or avulsion of the posterior sensory root of the ganglion. Cushing, I understand, has also lately begun to perform this operation in preference to total extirpation.

The failure of the intracranial operation from recurrence of pain has been due to reunion of the divided anterior branches when the Abbe operation was performed, or to incomplete removal of the ganglion when complete extirpation was attempted. To overcome these possibilities, Spiller, in 1898, suggested that the sensory root be divided. The success of this operation lies in the fact that unmedullated nerves do not become regenerated after division; and, as the nerve fibers comprising the sensory root of the ganglion are not medullated, regeneration after division does not take place. This has been proved experimentally by Spiller and confirmed by Ballance and Stewart[26] and Van Gehuchten.[27]

The difficulties of the intracranial operation do not lie in the exposure of the ganglion, but in the attempt to free it from its bed and in the fact of its close proximity to the wall of the cavernous sinus and the sixth nerve. For these reasons, it is asserted that division of the sensory root is the easiest method to carry out and will result in a still further decrease in the mortality.

For a long time intracranial operations were held in disfavor, because of the attendant high death rate. Tiffany's[28] estimated mortality, in 1896, of 22 to 23 per cent. for many years was the basis of the argument that the intracranial operation should be advised only in case of last resort. At that time the operation was in the developmental stage and as a consequence the risks were greater than they are at present. Hartley and Frazier place the mortality now at about 3 per cent. in competent hands. Cushing has had 2 deaths in 49 cases, while in the last 25 cases he has had no deaths. Abbe, in his last 25 cases, reports no deaths.

At present, when done by experienced men, the intracranial operation for trifacial neuralgia is not attended by more danger than is the average abdominal operation.

SUMMARY

Facial neuralgia may be classed as minor and major neuralgia. Minor neuralgias are due to peripheral causes, as carious teeth, disease of the antrum of Highmore, or nasal sinuses, by hypertrophied turbinates, nasal spurs, etc. The major neuralgias are probably due to a central lesion in the Gasserian ganglion, although, in these cases, the causes at times may have been peripheral.

The pathology of trifacial neuralgia is still indefinite. Although the investigation along that line has been very extensive, there still seems to be no definite lesion which can be demonstrated in every Gasserian ganglion removed. At least, some of the ganglia examined have given negative results, as reported by the pathologist. The lesion when present may be of a degenerative type, interstitial neuritis or a neoplasm (Frazier). Arteriosclerosis of the blood vessels is a common condition seen. In the peripheral nerves, there may be an ascending neuritis, which may secondarily affect the ganglion.

The treatment of trifacial neuralgia may be arranged under three divisions:

1. *Medical Stage.*—Medical treatment, often effective in the minor neuralgias due to constitutional conditions; includes also local treatment of nose and mouth; should not be persisted in too long without results.

2. *Peripheral Operation Stage.*—Peripheral operation, as neurectomy or avulsion, often effective in those cases in which one branch of a division or one division alone is affected. This stage includes treatment by injections of 80 per cent. alcohol in the region of the painful nerve, the results of which treatment have been very satisfactory. Cases for peripheral operation or treatment by injections should be carefully selected, and even in those cases there will be a certain percentage of recurrences.

3. *Stage of Intracranial Operation.*—Intracranial operations indicated in all types of major neuralgia where more than one division is affected and where medical treatment and peripheral operations have been tried and have failed. The operation advocated by Spiller, consisting of division of the sensory root of the Gasserian ganglion, seems to be the most rational one.

ABSTRACT OF DISCUSSION

Dr. Eugene S. Talbot, Chicago: I have had very little experience in the general treatment of trifacial neuralgia. Perhaps some of the most obscure cases are those in relation to irritations about the jaws and teeth. The most difficult cases I have been called on to treat are those in which there has been interstitial gingivitis for a number of years, with absorption of the alveolar process and in which the nerve fibers running into the apices of the roots have become exposed. In some cases it is very easy to diagnose these conditions, especially when the teeth are loose; on the other hand, there are obscure cases in which only one side of the alveolar process has been absorbed and the tooth still remains tight. The pulps are alive in these teeth, and it is only after exclusion of other conditions that we are able to locate the pain. In these cases the only thing to do is to destroy the pulps of the teeth. Other cases which are common and difficult to diagnose are those in which secondary dentine has developed in the dental pulp, or pulp stones. While all of us understand the pathology of the dental pulp, to a certain extent, yet from my experience in the study of this organ, I believe no one has a full idea of its pathology. It is a singular thing that within the last few years we have noted that certain conditions of the system such as autointoxication, blood poisoning, no matter whether due to drugs or systemic conditions, affect this organ, and it is one of the first structures to become involved in autointoxication. The pulp is an end-organ situated within the tooth. There are only one or two blood vessels and nerves entering the root of the tooth, where they multiply and divide and become a large mass, as compared with the entering nerves and arteries. This mass is enclosed in a crypt or cell. Toxins circulating in the blood, no matter what they may be, enter. The moment the pulp becomes engorged with blood there is stasis. Indicanuria, acidosis or any form of blood poisoning, causes this organ to become so involved that many of the diseases due to irritations are developed and deposits of secondary dentine, the formation of calcification islands, and the pressure on the nerve fibers in the pulp cause facial neuralgia. These are important pathologic conditions to the stomatologist. The average general practitioner would never locate the cause of the facial neuralgia in these structures. In cases of facial neuralgia, the stomatologist and the general practitioner should consult in order to locate the cause of the pain. The treatment outlined in this paper has become one of the fixed methods. I would like to hear more in regard to it.

Dr. M. L. Rhein, New York: As an observer I have carefully noted for some years what has been done in these cases, and from my own observations I have reached the conclusion that the general surgeon is prone to underestimate the number of cases of major facial neuralgia which develop from peripheral causes, which must originally have been minor neuralgias. This is the portion of the essay which is of especial interest to our Section. It is my belief from observation that the percentage of these cases that are ascending, as he puts it, is very much larger than is generally credited, and there is good reason for the fact that the general surgeon does not appreciate the number of cases that start in this manner. In the first place it is very rarely that he has the opportunity to come across these cases in the initial condition when it is purely of peripheral origin. But every stomatologist of any experience has had so many cases of this kind that have eventually terminated in the major form, that I feel we can all substantiate this point.

The question that is of peculiar interest to us is the prevention of major neuralgias by radically treating them in the condition that they present to the stomatologist when they are of peripheral origin. As I understand, Dr. Talbot was discussing the effect of the pathologic condition of the pulp of the teeth in these cases. It is in this very respect that I have been looking for the real etiologic factor of the peripheral origin of these cases for a number of years. Dr. Vida Latham has been very helpful to me for a number of years in mounting pathologic specimens of pulps of this nature which I have sent to her, and the microscopic examination of these pulps has borne out this fact. The peculiar relationship that the pulp has to the teeth when it is subject to unnatural irritation, is one that is bound to result in more or less of a pathologic condition at various periods of stress due to this irritating action, and it is my conviction that a great many dental operations are primarily at fault for this irritating and painful effect on the pulps of the teeth. In my experience the patients have been benefited to a great degree by absolutely eradicating the neuralgia when the case has been seen early enough before the disease has extended sufficiently into the nerve fiber itself, by the thorough removal of the pathologic pulp. In this respect I believe that when the offending tooth has been distinctly located, there has often been failure to produce the desired results.

It is absolutely essential in these cases that the pulp tissue should be removed to the very end of the root canal. In a majority of these cases crystallization of the pulp tissues has started and progressed to some extent, and this makes the removal of such pulp tissue in the multi-rooted teeth, where it generally exists, a very difficult matter, and instrumentation alone is never successful in satisfactorily accomplishing these results. When an operator discovers that he has located the real origin of this trouble in such a tooth, and is unable to remove every particle of the contents of those canals, there is only one recourse left, and that is to remove the tooth. In my experience the number of such teeth removed is very small, and only occurs when the irregularity of the roots in very great. The *x*-ray is of great help to the stomatologist, not only in giving him aid in diagnosing the offending pulp, but in informing him when he has satisfactorily reached the end of such roots. I could recite a number of cases that have passed into my hands after such pulp removal has been attempted and not successfully completed, in which, on completion by removing the contents from each of these canals, the result has been satisfactory. When the case once departs from this condition and reaches the unfortunate state described by the essayist as the major form, no method yet devised can be absolutely depended on.

I have paid special attention to the statistics regarding injection of alcohol, and I have found that my patient is relieved sometimes for a year, and even for two years; but recurrence of the major neuralgia finally ensues in a large number of cases treated in this way. I believe this to be due to the fact that the injection of the alcohol does nothing more than paralyze the nerve tissue involved at this period, and that when this action has been finally thrown off, as it generally is in time, the old condition recurs so far as major operations are concerned, therefore I am in hearty accord with what I judge is the technic of the essayist. I believe that when it is incumbent to have an operation of this kind, only the most radical offers any permanent results.

Dr. J. E. Power, Providence, R. I.: This error of faulty diagnosis is not confined entirely to the members of the dental profession. It is true that numbers of teeth are extracted for neuralgias which are not of dental origin; but this same error exists in the ranks of the neurologist, the surgeon, and the physician. By the very direction of their interests they are likely to see things from their viewpoint alone. I believe that the surgical procedure for the treatment of neuralgia should be the last thing on the program of treatment, and that while the dentist is bound in the interest of justice to refer his patient to the neurologist, the neurologist and physician have an equal responsibility, and they also are bound to refer such a patient to the dentist. While there are numbers of cases in which all the teeth have been extracted from a patient for relief of neuralgia with negative results, major operations are performed when proper examination and treatment of the teeth would reveal the cause and perhaps cure the disease. I believe that there is a very small percentage of those cases, which have become chronic, that can be traced directly to a dental origin, but the number is sufficient for us to give proper consideration to dental pains as a probable etiologic factor in neuralgia. Possibly Dr. Hussey will tell us whether or not there is any danger of tumor formation at the ends of the nerves when rubber has been interposed, and the relative danger of its presence. Since he has a wide experience in the medicinal treatment of neuralgia I shall be glad to have him relate his experience with aconitin.

The following is a brief history of a case which came under my treatment about four years ago. A patient, about 35 years old, suffered with neuralgia during varying periods, for five or six years. During these periods relief could be secured only by the administration of drugs. Examination showed a normal oral cavity. The lower third molar had been with difficulty extracted some three or four years previous. I performed an exploratory operation in the region of the extracted tooth which consisted of cutting through the tissues, chiseling through the bone, and establishing a communication with the inferior dental canal. Everything seemed normal, so I dressed the case, and in due time discharged the patient. Three years have now elapsed and there has been no recurrence of pain since two days after the operation. I do not know just what happened to cure the pain. We all know that in a process of repair of bone a callus is formed. I believe that in the extraction of the third molar referred to, the dentist had injured the bone. During the process of repair which followed a callus probably formed on the inner surface of that canal, which was just large enough to produce pressure on the inferior dental nerve. This of course is theoretical reasoning, but that the patient is cured is indeed fact.

Another case which will show the relative importance of dentistry to all other branches of medicine is the following, which had been diagnosticated trifacial neuralgia by several physicians, including a noted neurologist. The patient was prepared for an operation which would remove the second branch of the fifth nerve. The incision was made just below the orbit. When the bone was broken through pus flowed steadily from the antrum. The antrum drained and the patient was discharged cured. Is it not reasonable to believe that if the patient had been referred to a dentist or to a nose and throat specialist, the modern dentist or specialist would have examined the antrum by transillumination or other methods and even in the absence of any subjective symptoms would have made a positive diagnosis, thereby increasing the happiness of the patient.

Dr. M. L. Rhein, New York: My experience with the application of cold and heat and electricity in these cases is not very satisfactory; in the majority of cases they do not give the exact diagnostic results we desire. I have had success in reaching the tooth involved by a careful radiograph of each individual tooth in turn so as to not get one large radiograph of one side of the jaw but simply a non-distorted shadow picture of each particular tooth and its surroundings. It is generally at the point where the pulp with its circulation enters the root canal that the evidence of this inflammatory action becomes evident, and a careful study of most of these radiographs will show the effect of the inflammatory action on the alveolar structure in this neighborhood.

I do not mean to confine the dental irritation entirely to pulp effects. There are all kinds of dental disturbances that will act as peripheral etiologic factors in these cases, but nothing is so prone to do so as the condition in the case described by Dr. Powers. The number of cases due to the roots of the teeth impinging on the inferior dental canal itself has come to the obervation of almost every one of us, and this is also true of the effect of leaving portions of the roots of the teeth in the jaw after such teeth have been extracted. It has been my misfortune in a way to find myself at loggerheads with a number of men in my own locality, who are specialists in the extraction of teeth, for the simple reason that it has been the dogmatic practice of the majority of these specialists in extraction, that when they fracture the roots of the teeth (and there is no blame to be attached to them for that), and find that there is no purulent condition surrounding the roots of the teeth they calmly advise the patient that they need give no further consideration to this portion of the tooth left in the alveolus, and I have found it impossible at times to get such a specialist to remove such pieces. There is no factor more prone to produce peripheral irritation than a piece of root left, especiallly in the neighborhood of the inferior maxillary sinus.

Dr. U. C. Wendell, Milwaukee, Wis.: Not as a neurologist or pathologist, but as a general practitioner, I am much amused at the remarks made here about the general practitioner. In diagnosing these conditions, especially inflammation of the bone, cold and hot water may be used, and also the x-rays, but the response may be due to an inflammatory condition, or it may be absolutely reflex. The idiosyncracy of the patient ought also to be taken into consideration. Diagnosis of a remote disease of this kind is very difficult, even the most skilful physicians and surgeons have made the greatest mistakes in conjunction with the dentist. I have known of teeth being extracted indiscriminately without any relief of the condition. I recall an instance of a small root being left in the alveolar process. The tooth had been extracted years ago. This patient was under my care for two or three years, also under the care of a physician. He came in about six months ago and said this tooth was troubling him and it would have to be removed. I told him I did not believe there was any tooth trouble, that it was a reflex from some other source. The tooth was removed. Eventually I used the exploring needle and found the remains of a small root. I removed this also, but the man came back inside of several months with the same trouble; no doubt of reflex origin. He died of endocarditis.

The reflex action of the stomach and intestines is remarkable. I recall a patient in whom, when these stomach and intestinal conditions would come on, a swelling on the left side of his tongue would appear. This is outside of the discussion, but only goes to show how misleading cases may be.

Dr. E. A. Bogue, New York: During the past thirty years I have extracted or caused to be extracted only five good firm teeth. At present I have a case which has been going on for two years. The patient has been to nine different physicians, and no one has been able to discover the cause of his neuralgia. One man thought he found it in the inflammation of the Eustachian tube. He treated him and the pain subsided and stayed away for three weeks; then it returned. No one has since been able to stop that pain for more than three consecutive days. I do not think any one stopped it; it stopped itself. Thirty years ago in New York the practice of examination of each tooth separately was advocated and Dr. Bronson read a paper at that time advocating the isolation and careful examination of each tooth. I have myself subjected my teeth to examination by six or eight different men. One hurt me so much I did not get over it for two days. Not one of them, according to my idea, made a proper examination.

A surgeon, one of the professors of the Post-Graduate Medical College, brought a woman to my office with a swelling in the roof of the mouth. I suspected some trouble with the permanent molar on the right side. She said, "Impossible, I have just come from Dr. So-and-So a week ago, and he said my teeth are in perfect order." I found on the right side two cavities between every two teeth. Dr. Rhein intimates that we do not get the results we are after along diagnostic lines. It seems to me that we should outline among us here a careful examination of such a nature that it may be possible to those who can not afford radiographs of each case. That is not applicable to people at large. We have not time to put in that way, and the patient can not afford it; the great bulk of sufferers can not have it. A specialist and (so-called) oral surgeon described at Albany one time a case of pulp nodules, as he called it, which he had been able to diagnose causing facial neuralgia. He agreed with the patient that he would cure him for $1,600, and after an examination he found a big hole and put some arsenic in, and got his $800 to begin with. After the arsenic had been there twelve or fourteen days the slough was removed and he got his other $800. The facial neuralgia was cured.

I will confess my own utter inability to conceive any cause for the facial neuralgia which exists in the case which I mentioned. Transillumination has been tried. Every single tooth in the mouth has been either isolated by a rubber dam or cotton or both. There are a number of vacant canals. The patient's mouth has not been radiographed. I made the suggestion to him, but it has not been done to my knowledge. The pain is referable from time to time to the Eustachian tube on the right side. I feel certain there is no pulp exposure anywhere, no calcic abscess anywhere. I have not drilled into the roots.

I am glad Dr. Rhein has concluded that it is not wise to leave any pieces of pulp in the canal, and I hope he will agree that they are not easily removed in their entirety. I have seen several canals so small that it could not be removed at all.

Dr. M. L. Rhein, New York: I felt in the discussion of this subject we should not enter into the question of dental technic, but I do feel that so long as this is going into print I want emphatically to contradict the final statement of Dr. Bogue that it is impossible to remove the pulp contents of fine dental canals, and of the impossibility of removing pulp contents unless arsenic is used. I can demonstrate by means of radiographs of such cases the possibility of the stomatologist getting to the end of the finest canal, and I also want to protest emphatically at this time against the use of arsenic in treating these patients at all. I take an entirely opposite view from Dr. Bogue in this respect, because the very action of arsenic, its irritating effect on the tissues involved, is of such a nature that it is not an unusual etiologic factor in producing peripheral neuralgias.

Dr. F. V. Hussey, Providence, R. I.: I agree with Dr. Talbot in ascribing a great deal of importance to intestinal conditions. I believe thoroughly that the toxic state of the body resulting from a disordered intestinal condition has a great deal to do in many instances with so-called cases of facial neuralgia. The question of dividing neuralgias into minor and major types is simply theoretical for ease of discussion. We can not draw a sharp dividing line. I am of the opinion that the majority of these cases are of peripheral origin. The mere fact that we can not lay a finger on the peripheral cause does not necessarily mean that no cause is there. We know the body is constantly receiving peripheral stimuli, whether we are awake or asleep, and the fact that we are not always conscious of them does not necessarily exclude them.

Another thing which makes me think the pathologic findings which have been recorded in ganglia have been due to peripheral causes are that these findings are always very much more pronounced after preliminary peripheral operations; and in studying pathologic ganglia we should draw a distinction between ganglia which have been removed before peripheral operation and those removed after peripheral operation.

One point I wish to bring out is that medical treatment should not be indulged in too long without satisfactory results. The mere fact that a patient comes into your office and you prescribe for the pain and for the time being stop the neuralgia, does not necessarily mean that you are doing right by allowing that patient to drift along until he comes back. I think that if after three or four months of medical treatment a patient shows no signs of improvement he should be turned over to some one who can institute more radical means.

Thorough examination of the mouth, nose, eyes, ears, etc., should be made in all obscure cases. If we can eliminate disease of these structures we are so much better off.

While I believe that a cure can be promised much more definitely as a result of intracranial operation, we can not always do it. Other methods bring good results, and although they may be only temporary in the majority of instances, we can promise relief for a short time anyway.

The percentage of relief with alcoholic injection has been higher than with any other so-called palliative treatment. The mere fact that these cases recur five months, on an average, after the first injection, is no argument against the use of that method. It has been the experience of men using this method that recurrences after repeated injections become farther and farther apart.

Dr. Schlösser, who has had more experience than any one else, has taken the ground that by repeated injections you can offer a patient definite cure. It seems to me that the fact that the pain does recur is no argument against the injection treatment. I think Dr. Powers' theory in the case he recites, of a callus resulting from some injury to the jaw when the tooth was extracted, is a good one. We do know that certain exostoses will produce neuralgia, and there are cases on record in which removal has cured the trouble.

A STUDY OF MALNUTRITION IN THE SCHOOL CHILD *

[Editor's Note: The article with the above title, by Dr. E. Mather Sill, New York, appeared in The Journal, June 19, before the discussion thereon had been submitted to the speakers for correction. The discussion was therefore omitted at that time and is now presented below.]

ABSTRACT OF DISCUSSION

Dr. E. S. Talbot, Chicago: This paper covers so much ground that it is difficult to discuss the entire matter. There are some points, however, of unusual interest to stomatologists. We all know that adenoids occur at an early age; this is also true of deformities of the turbinates and other bones of the face, nose and jaws. If the child be poorly nourished during the period of development—from the first to the twelfth year—it stands to reason that these tissues will cease to develop and will not improve later in life; that is to say, they become arrested or excessively developed and remain so. Since the brain presides over the development of the tissues of the body, when the brain is not properly nourished the poorly nourished nervous system affects the blood supply, produces arrest of development of the face, nose and jaws, and malnutrition of the teeth. I have called the attention of the profession for the last four years to the fact that the teeth are involved in malnutrition. In the eruptive fevers and other constitutional diseases the teeth do not develop strength as they would in health. I think the essayist has brought out these conditions in a general way very well. We all know that the slum children of European cities, as well as of New York, are the most poorly nourished, have the greatest deformities of the face, nose, and jaws, with adenoids, hypertrophies, etc. It is in our province as physicians and dentists to aid these children toward being properly nourished and cared for, more especially during the early developmental years, and I am sure much could be done toward alleviating, or rather preventing, deformities of the jaws and teeth, which in turn would in a large measure improve their mental qualities.

Dr. W. C. Wendel, Milwaukee: In our city we have been endeavoring to ascertain whether the children in the poor wards in the school districts are more subject to dental caries than the children in the better wards. We find very little difference between these poorer children, who have probably never consulted a dentist, and those in the better districts. We investigated some of the other school districts, where they are not exactly the poorest, but the medium class, although in these districts some attention is paid to the teeth, yet we find practically the same conditions, viz., dental neglect. Carious teeth among these children is not even so great as it is among our "better class." Tuberculous patients often have extremely fine teeth. In other cases, in which the parents are apparently healthy, we find exceedingly carious teeth in the children. Investigations have not been carried on extensively enough in this direction to be of much value, but I am of the impression that there is something deeper seated in the civilization of our people than local causes. At the same time we can not deny that malnutrition has a great deal to do with the building up of the osseous structures.

Dr. E. A. Bogue, New York: Dr. Sill did not go far enough back in his discussion. We must go back to infancy to trace the history of most of these carious teeth in children. Dr. Cronin, as you all know, has done considerable work in the matter of examination of school children. He is even now arranging for a system of school-houses, desks and seats, and a dietary and general treatment for all children under the care of the teachers. He takes the ground that we are not sufficiently paternal in this matter. That, having taken charge of the children during the hours of so-called education, we should care for them morally as well as physically. He points out that if physical defects can be corrected, either by diet or anything else, that it will cost less to correct them than to suffer the absence of children so constantly from school. I have elsewhere taken occasion to allude to the fact that 40 per cent. of the absences of school children from school are due to dental conditions--preventable by proper care.

---

* Read in the Section on Stomatology of the American Medical Association, at the Sixtieth Annual Session, at Atlantic City, June, 1909.

Referring to the dietary, there is one thing that should be added here—the performance of function. There can be no perfect development of an organ unless its function is brought into use. If the masticatory apparatus is brought early into use, development will be far better than it is.

DR. E. S. TALBOT, Chicago: As to Dr. Bogue's criticism, I was not speaking of prenatal influences. No doubt the first period of stress is the most important to be considered. All deformities of the new-born are due, to a greater or less extent, to malnutrition, as the essayist has said. The effect, however, may be originally on the mother instead of the child.

DR. M. L. RHEIN, New York: I think Dr. Bogue has called attention to the most important feature of the whole subject. As I understand it, the essayist is endeavoring to elicit the sympathy and care of the state in overcoming this condition of malnutrition in school children. That the condition exists is most evident, and I think a careful investigation of the facts from an economic point of view will bear out the correctness of the theory that if the state intends to educate the children it can not overlook the fact that the children must be maintained in a proper physical condition to be educated, but I agree with Dr. Bogue that mere dietary considerations are not the all-important consideration. In other words, the condition of malnutrition can not be corrected by dietary measures alone.

Dr. Bogue has fittingly alluded to the fact that function of the parts must be maintained. It is impossible for us to correct the antenatal conditions. That does not lie in the power of the state. The conditions that tend to the producion of deformities and caries of the teeth exist, but the point remains that the malnutrition can not be corrected unless those conditions are primarily attended to. When these conditions exist, on account of the pain involved and the discomfort, the children will not masticate their food; so the first consideration is to put the mouths of these children in a condition that will make mastication possible, in order to produce the proper metabolic changes in the food to bring about assimilation and digestion. I think it becomes our duty to point out the fact that all the conditions resulting from malnutrition are to a large extent dependent on the proper mastication and insalivation of the food before it is swallowed, and that without the performance of these functions digestion and assimilation of the food becomes impossible. It is therefore essential that the organs of mastication be placed in a normal condition before that child will be able to use them properly.

DR. ARTHUR ZENTLER, New York: From information I gather from abroad, I find the subject has been gone into very thoroughly there—that they recognize the need of the state taking care of the mouths of the children. This is especially so in Germany, where Dr. Jessen and Dr. Rose have organized the school dental clinics, and the care of the children is begun in the kindergarten.

It seems to me that with proper care in infancy and in the kindergarten the question of the teeth of the public school children would be to a large extent solved. If we will do something toward the development of the maxilla and the mandible of the child in its infancy through proper nourishment, it will not be necessary, as a rule, to do anything in future years.

DR. G. I. BROWN, Milwaukee: I feel that we are under obligation to the essayist for the results of his great undertaking in examining 1.200 children on the East Side. He has dealt with their sociologic relation to our special field as affected by poor food, bad air, lack of air space, etc. It is plain that oral disease resulted, not only from immediate ill-nourishment in the instance of each individual, but that it went back to the time before he was born. If the mother did not have sufficient food or air, and was bearing ten or eleven children, one right after the other, it was impossible that these children could have been sufficiently nourished. Therefore, each of these factors have had an influence on the child. Dr. Wendell's point is well taken when he calls attention to the fact that it is not so much the kind of food,or the amount taken, but the benefit derived from what is taken, and, more than that, the part of the individual which is most benefited. We must not assume that only poor people have caries. After all, the question is, how much or how little of the food taken is of nutritive benefit to the individual and what effect this has on dental caries. I do not know any better way of getting at this than by such work as has been outlined by Dr. Sill in his paper. I think we are to be congratulated on having such a paper in this Section.

DR. W. C. FISHER, New York: I agree with Dr. Brown that this question is more of a sociologic problem than most of us realize. Unless one has worked in poor sections he can not appreciate the labor necessary for the production of such a paper as has been presented. These investigations are necessarily conducted in the congested districts, because it is here that we find these conditions to such an alarming extent. And how can it be otherwise under existing conditions? How can a laboring man who is fathering from seven to ten children earn enough money to procure food and shelter for them? It is impossible. It therefore sifts back to the sociologic problem. How can we better the condition of that family so that that man can provide for his family?

Dr. Sill compares conditions here with those in England, Scotland and Germany. He takes nations in which the people are all of one nationality. It is far easier to school a nation by its own people. The East Side of New York is made up of the most conglomerate collection of humanity imaginable. You can not teach these people—you can not talk to them; they speak so many different languages—hence the only way is to legislate for them. In other words, these immigrants—for they are mostly immigrants or children of immigrants—come in by tens of thousands and go to these already congested districts. The father can not get work; he can not provide food; and as a result we have these physically impoverished children. The whole remedy, it seems to me, will be found in the word "scatter." If these people could be distributed to the less congested districts, where they could find employment and better air, you would find they would provide food for the children, and the children would find a way to masticate it, and if they complain of the toothache they would be sent to the dentist. Those people are human beings. Give them proper environment and they will improve. We can not expect to improve them under existing conditions. They are massed together so closely it is like taking an ant hill and pushing it down in one place and it comes back in another. Good tenements won't do the work—get these people out of the tenement district. Dr. Sill states that within a few miles there are many thousands of people, enough to make a city. The moral tone is bound to be low, and the mind affects the body. There can not be a healthy body with an unhealthy mind. Until you change their conditions you can not help them. You can give them food every fifteen minutes and they will not profit by it.

DR. W. C. WENDELL, Milwaukee: Dr. Fisher spoke more on sociologic and moral lines. What I would like to know is: Do you find more caries in the mouths of this class of people, and more pathologic conditions, irregularities, adenoids and contracted arches, than you do in the better-fed class?

DR. E. A. BOGUE, New York: One of the British writers on the subject of adenoids called attention to the fact that on the equator about 3 per cent. of the population had adenoids, while in Greenland there was something like 40 per cent. I talked with Dr. Grenfell of Labrador, the missionary-physician, who told me that he thought there was over 30 per cent. in Labrador. There the people live largely on blubber. In the north of Scotland and certain parts of Germany, where the people eat oatmeal cake, which is hard and requires mastication, you will find good teeth and few adenoids—that is, among the older people. I have not examined the children. But in the generation of today you will find "store teeth." The young folks eat oatmeal, but they do not eat the hard cakes. This is not universally so, but to a large extent the young people eat too soft foods. Our calling is still one of repair; we have not been able as yet to exert the prophylactic measures to prevent these conditions of early decay of the teeth. We are still searching.

Dr. M. L. Rhein, New York: I think Dr. Bogue is just a little wrong in saying that our calling is one of repair. While I am ready to admit that the ideal state of prophylaxis has not been reached in stomatology, yet there is no specialty in the entire field of medicine that has the possibility that we have in stomatology. Of course, the abnormalities of birth that come from defective parentage are those that can not be prevented after the child is born. These are economic and sociologic questions that are not under consideration; but, when they can be placed aside, the future of stomatology lies exclusively in prophylaxis and not in repair. I also disagree strongly with Dr. Fisher's remarks on this subject when he says that it is possible to scatter any such heterogeneous population by any enactment of legislation. In the first place, I know the East Side of New York. I have studied it very closely and I want to say that the people there are employed in occupations—they could not remain there if they were not. It is true their employment is such as is found in London in similar localities, but his prescription is an impossibility on the start because there is use for the employment of these men. If he would modify his statements and say that efforts to induce some portion of this population to be moved to the suburban districts were enforced it would be beneficial. Now, such efforts are being made constantly in the City of New York, but the impossibility of doing anything of this kind effectually is self-apparent. The improvements in the housing of this population have been going on for years, and a great deal of benefit undoubtedly accrues from efforts in that direction. The old tenements, such as were a disgrace to the city, can never be re-erected in the City of New York. The law prevents anything of that kind in the future, and there is no question of a steady improvement in that direction, but I do insist on the point, with all due reference to the value of proper air, ventilation, etc., that it is impossible to get the benefit of proper growth and nutrition unless primarily the dental organs are in a condition of normality, so that they will be used by the child. Consequently, I claim that it is the duty of the State, if it intends to educate the child, to see that the teeth are in such a condition that the child will masticate its food, just as it is the duty of the State to see that the eyes are in such a condition that they can be used normally; and I believe, when you come to sift this whole matter, that that is the most important point that will be left for consideration in order to accomplish the results that the essayist is looking for.

THE TONSILS AND THE TEETH [*]

[Editor's Note: The article with the above title, by Dr. G. Hudson Makuen, Philadelphia, appeared in The Journal, June 19, before the discussion thereon had been submitted to the speakers for correction. The discussion was therefore omitted at that time and is now presented below.]

ABSTRACT OF DISCUSSION

Dr. Frederick Lester Stanton, New York City: Dr. Makuen suggested the possibility of the enlarged faucial tonsil having a direct mechanical effect in pushing the alveolar process and teeth of the lower arch forward of their normal position, and that he has been unable to find anything similar to this theory in the literature of this subject. There has, however, been a similar theory advanced. In order to relieve the pressure on the enlarged faucial tonsil, the child has held the mandible forward, causing the teeth to lock in a malrelation, and in consequence the mandible has been developed to meet the needs of these unbalanced muscular forces, in this way producing a protruding lower jaw.

Dr. Charles K. Teter, Cleveland: I am much interested in this subject, as I have been closely connected with this kind of work for the last six years, but I do not entirely agree as to the necessity of complete extirpation of the tonsil, that is, in the majority of tonsil operations that are done by throat specialists to-day. I have worked with eight or nine leading specialists, and there are probably four or five who do complete extirpation every time they operate; and the others use their judgment in the matter. I have been in a position to compare the results of these operations, and when it comes to my own children—I have three and two had to have their tonsils removed—I prefer tonsillotomy. One child, 8 years old now, was operated on four years ago and has never had any trouble since. The other, about 4 years of age now, was operated on about a year ago. In children it is necessary to give a general anesthetic, and a tonsillectomy under these circumstances comes near to being a major operation; the hemorrhage is profuse, and it takes some time to do it properly. In an adult it is different, because complete extirpation may be done under a local anesthetic. I have had opportunity to follow up a good many cases, and I find in the majority of cases in which tonsillotomy was performed the after-results are just as good as in tonsillectomy.

Complete extirpation does not always end the trouble. Cicatricial tissue forms, which one of the surgeons states gives him more trouble than leaving part of the tonsil.

I have known in the last year of four cases of hemorrhage in which the patient almost lost his life, and the tonsillar pillars had to be ligated to stop the hemorrhage; so I do not think we should do a tonsillectomy in all these cases. I prefer tonsillotomy in children; in adults, if they have diseased tonsils, I prefer complete extirpation under local anesthesia.

Dr. G. V. I. Brown, Milwaukee: I had the pleasure of seeing Dr. Makuen operate last summer, and I am willing to subscribe to whatever he says with regard to methods of operation in tonsil removal. One point in his paper which I believe to be important has not been touched on in this discussion, that is his reference to tonsils which are enlarged, but not visibly so, because they are buried between and behind the faucial pillars. Recently I was asked to examine a patient who seemed to have rather small, certainly not large, tonsils, and a few minutes later two enormous tonsils were placed in my hands that had been dissected out from under the overlying tissue for the same individual. Undoubtedly, tonsils such as these would cause the conditions Dr. Makuen has called attention to, and unfortunately, if dentists depend on themselves for diagnosis, such conditions would often not be discovered sufficiently early to prevent their leading to serious pathologic results.

Dr. E. A. Bogue, New York City: We all know that children whose tonsils are enlarged will close their teeth in such a way as to promote an irregularity of the dental arches. I happen to possess models of two children taken at different periods of their lives during three or four years, and I think that the progress from almost a normal condition to very great abnormality is evidenced very clearly in those models. It is exceedingly interesting to me to hear Dr. Makuen bring that very point up. I have never heard it alluded to before. I am glad that Dr. Makuen spoke of the vicious circle—bad tonsils and bad arches. This is indeed a vicious circle, and as the proceedings of this section will be read more or less by medical men and by dentists, I think that is an important point which has been pretty much neglected. That the attention of dentists is being more and more directed to the entire oral cavity is unquestioned.

Dr. E. S. Talbot, Chicago: As to infection of the alveolar process referred to, I do not quite understand just what Dr. Makuen means by the relations of the tonsils to the teeth. There is no question but what there are germs in diseased tonsils, and there are germs in decayed teeth, but how the tonsil can affect the teeth I do not understand. But there is this point in relation to the teeth which I think Dr. Makuen intended to bring out, and that is that in all patients we have more or less interstitial gingivitis, inflammation of the alveolar process and the gums. We can not have infection of those structures without first an inflammation, then there must be pus germs to infect the part, which would be understood as pyorrhea alveolaris. When the tonsil becomes infected with pus germs we have interstitial gingivitis producing pyorrhea alveolaris, and on treating the tonsil or removing it and afterward curing the pyorrhea alveolaris, it does not occur again, although the interstitial gingivitis may remain. The vicious circle is all important, especially in younger children; the effect on the general system—on the blood and the nervous system is vicious. It prevents growth and development of the jaws and the face and nose as well. We all have seen children develop very rapidly after correction of these conditions.

---

[*] Read in the Section on Stomatology of the American Medical Association, at the Sixtieth Annual Session, at Atlantic City, June, 1909.

DR. G. HUDSON MAKUEN: I had expected that more would be said in the discussion with reference to my note on the effect of hypertrophied tonsils on the alignment of the teeth and the development of the alveolar arches. I have been able to find no reference to this point in the literature, and I should have liked to have had a fuller expression of opinion on it. It should be borne in mind that these large tonsils are sensitive to pressure, as a rule, only when they are acutely diseased, and only a little pressure sometimes is required to determine the position of the teeth and the shape in the alveolar processes. The relation between the faucial tonsils and the cervical glands is a very close one, as has been shown by anatomic dissections, and one observer, after the removal of some cervical glands, actually passed a probe from the wound in the neck into the faucial tonsillar fossa. The other day I removed the tonsils of a small child having a bunch of cervical glands nearly as large as my fist, which almost entirely disappeared in the brief space of one week after the operation. In other cases glandular enlargements in the neck may and do occasionally increase immediately after operations on the tonsils, which fact shows the close relationship existing between these structures.

As to the comparative merits of tonsillectomy and tonsillotomy, I would say that there seems now to be but little discussion. In the recent meetings of the two largest American laryngologic societies, only one man of the three hundred lifted up his voice in favor of the partial removal of the tonsils, and he was one who had long been a practitioner of the specialty, and he was loath to give up his older methods. Only diseased glands, of course, should be removed, and when we have once decided on the operation, I think we should remove all the diseased tissue, and we should not be deterred because the operation is more difficult or because there is likely to be more hemorrhage. With reference to this last objection, I may say that there are those who think the hemorrhage is greater after tonsillotomy than after tonsillectomy, because blood vessels cut through in fibrous tissue do not contract so readily as those not so surrounded. The operation is not a simple one, but requires some skill and dexterity. The removal of only a portion of the tonsil, beyond giving more breathing space, may do more harm than good by making of the diseased stump a more fruitful source of infection.

Dr. Brown's point with reference to submerged tonsils is a good one. The tonsil that protrudes into the pharynx and hangs, as it were, by a pedicle, is probably the least harmful, because it has better drainage and it does not admit of so much absorption of infected material in the general system. In reply to Dr. Talbot, I am of the opinion that foul detritus exuding from diseased tonsils must have a more or less injurious effect on the teeth, and from what he has just said, I gather that he agrees with me thoroughly on this point.

Clinical Notes

GONORRHEAL EXOSTOSIS OF THE OS CALCIS

REPORT OF CASES

GILMAN J. WINTHROP, M.D.
MOBILE, ALA.

Baer,[1] in 1906, called attention to certain cases characterized by pain over the plantar surface of the heel, due to a chronic inflammatory change, of gonorrheal origin, located in the flexor brevis digitorum muscle, with secondary new formation of bone or exostosis at the attachment of this muscle to the tubercle of the os calcis.

Nobl,[2] of Vienna, had previously noted exostoses on the posterior surface of the os calcis, due, he thought, to inflammation of the sheath of the tendo Achillis, and suggested that they might, perhaps, be of gonorrheal origin, but this was not proved.

L. Jacquet[3] and Painer[4] also described exostoses on the posterior calcaneal surface, but were unable to determine the etiologic factor.

Ely[5] refers to a condition he names "gonorrheal foot," and states:

> It is characterized by extreme sensitiveness, usually in the soles. A history of a comparatively recent infection by the coccus of Neisser can be obtained, and the urethra will be found affected. These feet have something about them that immediately makes one suspicious, but further than the extreme sensitiveness and the fact that the patients walk as if they were treading on eggs, I can not tell exactly what it is. Even the pathology is a matter of doubt, for the condition is not one to justify an operation, and the diagnosis is a mere matter of empiricism.

It is quite possible that he refers to cases of gonorrheal exostosis, but he reports no skiagraphic or pathologic findings.

The paper of Baer,[1] I believe, first definitely describes and proves the gonorrheal origin of the condition he terms "gonorrheal exostosis of the os calcis."

Following the report of six cases by Baer, Jaeger,[6] in 1908, reported eleven others, and Davidson[7] adds the eighteenth case. I wish to add to this number the histories of two cases.

This affection is probably not uncommon, but the chief symptom, that of pain under the heel, is usually ascribed to some other condition—flat foot, tuberculosis, osteomyelitis or sarcoma of the bone, neuritis, bursitis, chronic rheumatism, rheumatoid arthritis, Schaffer's foot and the various other conditions associated with painful heel—and the close relation of an existing or previous gonorrhea is overlooked.

PATHOLOGY

Baer[1] believes that the initial process is located in the flexor brevis digitorum muscle and extends down to the os calcis. The chronic inflammatory process produces, first, exostotic growths at the attachment of the muscle to the tubercle of the os calcis and, secondarily, other bony growths may develop on the sides and posterior surface of the calcaneum or in the adjacent tendons. Jaeger states that "pathologically the process is an ossifying periostitis." Gonorrheal arthritis and exostoses between and along the vertebra may be coexistent. Baer demonstrated gonococci by culture in 1 and in sections in 2 of 4 cases examined. Jaeger reports positive findings of gonococci in one case. Cultures taken in Davidson's case proved to be sterile.

SYMPTOMS

1. *Pain.*—This, the chief symptom, is referred to the plantar surface of the os calcis, is very limited and present only when the patient bears weight on the foot or on direct pressure over the exostosis. Both feet are generally simultaneously affected. Usually there is no

[7] Davidson: Med. Rec., Oct. 3, 1908.

pain on moving the foot, unless secondary osteophytes be present about the attachment of the tendo Achillis or mediotarsal joint. Pain about the ankle, knee or in the calf muscles may occasionally occur, because of strain on muscles or tendons from the unnatural gait of the patient.

2. *Gait.*—The extreme tenderness of the heel causes the patient to throw the body weight forward to the ball of the foot and gives a tiptoeing gait. His steps are slow and careful.

3. *Deformity.*—There is but little noticeable deformity. Periosteal thickening often produces a swelling on either side of the calcaneum. Occasionally very large exostoses may be felt on the bottom of the os calcis.

DIAGNOSIS

The complaint of pain in both heels and admission of an existing gleet or attack of acute urethritis some months previously, generally three to nine months, are suspicious. These, with the presence of the tender spot over the tubercle of the os calcis, absence of acute signs of inflammation and the gait should lead to an *x*-ray examination. Skiagraphs show a pointed or slightly bulbous bony growth springing from the tubercle of the os calcis and varying in size from "that of a pea to that of a marble." Occasionally there may be multiple exostoses. All the cases recorded have occurred in adult males. The exostoses are commonly bilateral.

TREATMENT

All measures save operative seem of little avail. Baer reports five patients operated on with cure. Jaeger obtained excellent results in six patients operated on. Davidson's patient was fully relieved by operation.

An incision is made along the inner side of the heel parallel to the plantar fascia, exposing the lower border of the os calcis. The tissues are retracted and the exostosis chiseled or curetted away. The wound is closed with silkworm gut without drainage. Baer also used in several cases a plantar incision directly over the exostosis. Jaeger also employed the plantar incision and introduced a cigarette drain for twenty-four hours. The lateral incision is probably the better, as it admits of clearer exposure and the resulting scar is not subjected to pressure as when located on the bottom of the heel. Drainage is unnecessary, as there is but little bleeding and the wounds heal by first intention.

CASE REPORTS

Case 1.—*Patient.*—J. S., white man, aged 19, was admitted to Gouverneur Hospital,[8] New York, Sept. 11, 1907. Family history unimportant. Patient had measles and pertussis as a child. He was an electrician and was not subjected to an unusual amount of standing or walking.

Present Illness.—Patient had an attack of acute gonorrhea three months before admission, which was treated for several weeks. Three weeks before admission he noticed slight tenderness in both heels on walking. Tenderness had grown steadily worse and latterly in the evenings he had had some pain in ankle and running up to knee. The heels were never red or swollen and pain was noticed only on standing or walking.

Examination.—Patient was a rather poorly nourished man; general examination otherwise negative except for the presence of enlarged inguinal glands on both sides and for the tenderness under heels. On under surface of both heels there was marked tenderness over a very limited area. No swelling, redness or deformity was to be made out. Patient walked with great pain and threw his weight forward on to ball of foot, keeping heels free from the floor. Temperature, pulse and respiration were normal. Blood examination was normal; urine, normal except for presence of "clap shreds." Skiagraphs showed presence of exostoses on under surface of both ossa calcanei. Gonococci were determined in pus cells from the urine. The exostoses were, unfortunately, not examined for organisms.

Operation.—Ether. Right heel: Incision on inner side. Os calcis exposed and exostosis (½ inch long and ⅜ inch high) removed. Wound closed without drainage with silkworm gut. Left heel: Incision on plantar surface of heel; exostosis, about same size as in right foot, removed. Wound closed with silkworm gut. No drainage.

Postoperative History.—Wounds healed kindly and patient discharged November 28. All symptoms relieved. The pain in ankles and knees of which patient complained was evidently due to muscular strain produced by his abnormal gait in effort to relieve heels of pressure. This pain disappeared entirely after patient was kept in bed.

Case 2.—*Patient.*—X, man, aged 20, was admitted to Gouverneur Hospital,[9] New York, April, 1908. Family and past history unimportant.

Present Illness.—Some nine months before admission the patient contracted an acute gonorrheal urethritis. He was treated with urethral injection until the acute symptoms abated, when treatment was discontinued. He noticed a slight mucoid discharge in the mornings for some time after stopping treatment. About four months before admission he felt slight tenderness in heels when he first walked in the morning but this gradually wore off during the day. Lately this tenderness had grown worse and persisted all day, seriously interfering with walking. He had been treated without improvement for flat foot and rheumatism.

Examination.—Patient was a fairly well-nourished young man. Thoracic and abdominal organs were normal. Prostate was slightly enlarged and firmer than normal. Inguinal glands, especially of left side, were enlarged. Urine showed gonorrheal shreds in first glass; second and third glasses clear. On plantar surface of both heels there was marked tenderness on pressure and walking was quite painful. No redness, swelling or deformity was noticed about heel; no pain on movement of foot. Gram-negative diplococci were determined in cells from urine. Skiagraphs showed a pointed bony growth springing from the tubercle of both ossa calcanei.

Patient was treated with hypodermic injections of gonorrheal antitoxin for three weeks but without improvement.

Operation.—May 4, 1908. Ether anesthesia. Right foot: Incision over inner side of right heel exposing exostosis, which was chiselled away. Wound closed with continuous catgut suture. No drainage. Left foot: Plantar incision over tubercle of os calcis. Exostosis, not so large as in right foot, was easily removed with rongeur forceps. Catgut closure and no drainage.

Postoperative History.—Wounds healed by first intention. Patient discharged on twentieth day after operation. Very slight tenderness persists under left foot, probably because of scar.

204 Conti Street.

HAIR SICKNESS

H. F. GILLETTE, M.D.

CUBA, N. Y.

I wish to call the attention of those who are interested in the various phases of serotherapy to a disease which affects workmen in hair-cleaning mills. The hair from various animals is received at the mills in bales which are opened and the hair is put into machines which separate the hair from dust and other foreign material, and the workmen necessarily inhale much of this dust which, in part, is the dried secretion of the sudorific glands of the animals from which the hair came.

---

[8] I am indebted to Dr. H. M. Silver, visiting surgeon to the Gouverneur Hospital for permission to publish this case.

[9] I desire to thank Dr. Edward L. Kellogg of New York City for permission to report this case.

The workmen recognize a disease, or reaction which they call "hair sickness," which comes on from 3 to 5 days from the time a new workman is first exposed to the dust. The sickness is characterized by a severe chill which comes on in seeming health, and a fever which may reach 103 to 104 F. The patient experiences severe pains in the head, back and extremities, and has nausea and vomiting. He usually is confined to the bed for a week or more. When he recovers he is immune to the disease so long as he continues to work about the hair, but if he leaves the mill for a year or two his immunity ceases and he experiences the reaction again if he resumes work about the hair. The mill hands claim that hair which has been removed by clipping machines from live horses is more toxic, and that the reaction comes on earlier and is more severe than that of other animals.

Workmen who are subject to asthma, or who look for a return of hay-fever on a certain date, are quite sure to be free from the asthma and hay-fever while working about the hair, but the immunity ceases after a time if they leave the mill and enter other work. Horse serum is used in the human subject because its effects are milder than the serums from other animals, yet if the observations of workmen are correct the dust from the horse is more toxic than that from other animals. One explanation of the seemingly increased toxemia from the dust from horse hair is that it comes usually direct from the clippers and with all the dust retained, while the cow hair which is received has been passed through a tanning process which washes out the dust.

It is possible that something on this subject has been reported, but I am not able to find any reference to the reaction or toxemia described.

[EDITOR'S COMMENT.—This interesting account of what seems to be a special "trade disease" suggests the possibility that the symptoms described may be due to an infection rather than to an intoxication by any constituent of the hair. The sharp rise in temperature, the chill, and the general symptomatology are distinctly more in harmony with the course of an infection than with any intoxication with substances of animal origin. This possibility is made more plausible by the statement that the hair from hides that have been tanned seem less toxic than that derived from living animals. The process of tanning would naturally destroy the bacteria. Cultures from the blood might throw light on the etiology of the disease, which is assuredly well worthy of investigation.]

USE OF APPENDIX TO SPLICE THE URETER

HARVEY P. JACK, M.D.
CANISTEO, N. Y.

During some recent operations in the pelvis, in which the ureter was bared during the dissection, it occurred to me to see if it would be possible to use a healthy appendix to splice the defect caused by any injury of the ureter or by the involvement of an inch or two of it in cancerous disease, requiring the sacrifice of that portion. I found that I could bring the appendix over this place in the ureter without traction on its mesentery. Since these operations, whenever I have opened the abdomen either for removal of the appendix or for any other operation, I have attempted to ascertain if it were possible to bring the appendix over the ureter. My investigations have confirmed my opinion that it would be possible in a right-sided injury of the ureter to splice the defect with a healthy appendix. So far as I know this is an original idea.

PELLAGRA IN ARKANSAS

O. L. WILLIAMSON, M.D.
MARIANNA, ARK.

The following case came under my care July 28, 1909:

Patient.—Virginia C., negro woman, aged 23, field hand, married, has child 4 months old. Family history negative. Patient has had attacks of malaria; no syphilis; has always used corn-bread in preference to other breads.

Present Illness.—This began about May 20, 1909, with "sore mouth." Patient had considerable difficulty in eating on account of pain. About June 1 a skin lesion appeared on the proximal side of the palm of the right hand. This was followed in about a week by a similar lesion on the dorsal surface of the left hand. These lesions increased rapidly in area. They were thought to be due to burns, although patient could not remember having burned herself. The lips soon became affected with a moist lesion. Patient began losing flesh rapidly but continued to work in the fields. About July 10 diarrhea began. The stools contained blood and mucus but were not accompanied with tenesmus. She had no nourishment for the baby after July 14. Nausea and vomiting began July 25.

Examination.—On July 28 I found patient weak and emaciated. The dorsal surfaces of both hands were covered with a dark lesion that appeared somewhat like an old burn. The skin was thickened, rough, and very black in places. Portions of the surfaces were covered with crusts while others were entirely raw. The condition was exaggerated on the knuckles and between the fingers. There was some pus between the fingers. The palms were also affected but the lesions there were drier and there was considerable exfoliation. There were no raw surfaces on the palms. Both hands were slightly swollen. The affected areas were symmetrical in size, shape and position and extended from the tips of the fingers to about the juncture of the lower and middle thirds of the forearms. There were painful exfoliating areas on the lips. The tongue was red, smooth and painful. Stomatitis was evident. The temperature was 101 2/5, pulse 150, respiration 20; heart rapid but otherwise normal; lungs, liver and spleen normal; abdomen slightly tympanitic and tender. The skin of the abdomen appeared somewhat like that on the doral surfaces of the hands, being thick, rough and abnormally dark. The pupils were equal and reacted to light and accommodation. There was slight decrease in tactile sense over affected areas. The knee-jerk was normal on the right side but decreased on the left. There was no ankle clonus and nothing abnormal about the gait. The patient's mind was clear and she had neither headache nor vertigo. She complained of being tired, weak and thirsty; had pain in back of neck and itching of affected parts. She was restless at night and had had chills the past three nights; was still suffering from nausea, vomiting, loss of appetite and diarrhea. She had lost thirty pounds since June 10 and had become too weak to sit up long at the time. The urine contained neither albumin, casts nor sugar, the only abnormality being an increase of indican.

Examination of Blood: Hemoglobin, 95 to 100 per cent.; prolonged search revealed one estivoautumnal parasite. Polychromatophiles and macrocytes present; blood platelets decreased. Differential leucocyte count; small mononuclears, 23 per cent.; large mononuclears, 15.3 per cent.; polynuclears, 59.2 per cent.; eosinophiles, 2.4 per cent.

PAROXYSMAL TACHYCARDIA ASSOCIATED WITH ANGINAL SYMPTOMS

T. WERTZ, M.D.
PRINCETON, IND.

This condition began in my own person about six years ago, first with the loss of a heart-beat about every five to twenty beats, more particularly after meals and after exercise. There was little or no discomfort from the irregularity. Repeated examination of the heart by experts failed to discover any heart lesions. This condition continued for a period of about four years without any apparent increase in the irregularity and no other subjective symptoms.

ANGINA APPEARS

About two years ago anginal symptoms with tachycardia first made their appearance. At first the pain about the heart radiated into the left shoulder, and in a short time subsequent into both shoulders. This rapid heart and pain was always brought on by walking at my usual pace for a distance of two or three blocks, and at these times the heart would be very irregular. As time went on these paroxysms were excited by walking, by any sudden movement or mental excitement. At the height of this trouble night attacks occurred some time after retiring for two or three times at intervals of several weeks. These night attacks would last half an hour or more, the heart beating very rapidly—four or five times faster than normal. The attacks brought on by exercise usually quieted down after five or ten minutes of rest. With these paroxysms the heart irregularity was very great, losing a beat every three or four pulsations. After this condition had lasted about a year it began slowly to abate in severity so that now after two years the irregularity and pain about the heart is very much less.

Exercise immediately after a meal will set the heart to going; but an hour or more after the meals I can walk at a moderate pace for a mile or more with little discomfort. I feel perfectly well and comfortable when at rest bodily and mentally, with usually little or no irregularity of the heart and about 70 beats a minute. But this cardiac quietude is easily disturbed. In the morning hours before rising or with some mental emotion there will be a sudden jump of the heart beat to many times the normal. This unsteadiness seems to be associated with the congestion of the brain from the long recumbent position. Every morning this rapid heart action is a prominent factor while dressing. In the last six months a soft systolic initial murmur has developed without any other apparent heart lesion. All other bodily functions are normal and well performed. I am six feet tall, weigh two hundred pounds, am past 60 years of age and have always heretofore enjoyed good health and come of a long-lived family.

I have tried many forms of treatment with drugs, but without any apparent benefit, except during the first year of the severe symptoms. These were held in check or slightly modified by nitroglycerin pellets if taken before walking. For the last year all drugs have been abandoned. A daily morning cold tub bath will relieve the restlessness and steady the heart.

In addition to this I have discovered that the rapid heart can be instantly brought to the normal rhythm by grasping both carotids with the thumb and forefinger and compressing them against the larynx or trachea. The instant this compression is made the heart makes a single vigorous impulse and at once resumes its normal rhythm. This has been a great boon to me for the last year, as the galloping heart can at once be brought under subjection. The vagi seem to have lost control of the heart's action and this organ is like an engine without a governor. The compression of the carotids increases the blood pressure in the heart which, perhaps, through a better nutrition, steadies the cardiac ganglia. What the exact condition is and just how this compression of the carotids acts beyond increasing the blood pressure I am not prepared to say. But so far as my own case is concerned it has robbed this terrible condition of its sting. I place this statement on record hoping it may be of equal service to others in like conditions.

A CASE OF APPENDICITIS OF TWENTY YEARS' STANDING *

J. H. CARSTENS, M.D.
DETROIT

Clinical History.—Reported by Dr. F. E. Bowman. The patient, Mrs. E. W., aged 60, appears well nourished and robust. Her trouble, which began about the age of 40, was diagnosed as peritonitis and in about five months terminated in an abdominal abscess in the region of McBurney's point, which was lanced. It remained open for about three weeks. After this the right thigh was flexed on the abdomen for about eighteen months. For about eight years thereafter the patient's health was good. Then she fell from a hammock and injured her right hip. One week later an abscess appeared at the site of injury. Almost immediately after the fall, pain was experienced again at McBurney's point. The patient connected this pain with the abscess opening on the hip. In about three weeks she was about her housework in fair health.

After that time there were from one to three recurrences of the abscess openings on the hip, which healed in from three weeks to three months. About ten or twelve years ago she had an operation for appendicitis. The surgeon opened the abdomen at right iliac region and reported that "appendix had sloughed off." He likewise made a long incision on the hip at the site of the abscess opening. Recovery did not take place until ten months later. During convalescence repeated incisions were made on the hip and two on the abdomen, tubes being inserted in both abdominal and hip wounds. A tube was retained in the posterior wound for three years. This brings the history up to some seven years ago. Then for three years abscesses formed from one to three a year. Poultices were applied and the lance used in every instance. For the past four years no abscess formed and the wounds closed. An abdominal hernia developed at the old abdominal incision in the meantime. In September, 1907, another abscess formed, which was opened. It drained freely at times; then would close to reopen in four or five days. In this condition the patient consulted Dr. J. H. Carstens on Dec. 7, 1907.

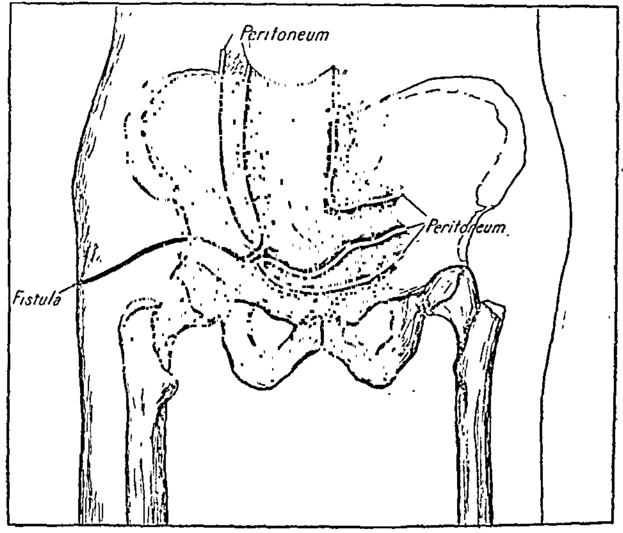

Diagram showing structures involved in an unusual course of an appendiceal abscess.

Operation (December 10).—An incision was made over the hernia. The cecum was adherent to the right iliac fossa and was with difficulty brought to view. A stump of the appendix, about three-fourths of an inch long, was still thoroughly adherent all around to the posterior peritoneum, but the center had passed through the peritoneum and opened behind the peritoneum into the fascia and muscles found in this locality. From there started an opening back of the peritoneum upward, passing over the ilium and then passing downwards around the hip joint, opening just back of the great trochanter. The remnant of the appendix was loosened from its adhesions. The peritoneum was stripped back, making a cuff to the cecum, the small stump of the appendix cut off, and the hole in the cecum closed with fine catgut. First, the muscles and mucous membrane were carefully brought together, the cuff of the peritoneum also sewed and all this amplified by Lembert's suture. A small rubber drainage-tube was then inserted in that posterior opening up to the crest of the ilium and then downward to the skin opening. The tube reached just up to the peritoneum, but not into it. The hole in the posterior peritoneum where the appendix had been was now carefully closed in a similar way to hole in the cecum and amplified with Lembert's suture. The peritoneal cavity was closed. I then resected the muscles where the hernia was, in the flap-splitting manner, put them well together with catgut, and closed the rest of the incision and skin without drainage.

---

*Read at Northern Tri-State Medical Association, Toledo, July 13, 1909.

Postoperative History.—The patient made an ideal recovery. The rubber tube at the external opening was gradually withdrawn and in twelve days everything had healed perfectly. The patient has remained in good condition since that time.

Analysis of the case now with a better understanding shows that the appendix (probably two-thirds of it) reached back of the peritoneum originally. I described such cases ten years ago.[1] This part back of the peritoneum became inflamed and suppurated and sloughed off, the pus burrowing, and finally the abscess opened just in front of the crest of the ilium. Later on it burrowed downward and opened near Poupart's ligament, as shown in the schematic sketch I have made.

The adhesions and cicatrices offered more resistance than the loose cellular tissue in the iliac fossa; hence thereafter the burrowing continued over the ilium, then downward around the hip joint, and the abscess would open there. It was, indeed, a puzzling case. Any one looking at the different scars now would naturally make the diagnosis of a former hip-joint disease. A number of times the woman had been apparently well. Everything had healed, but as the result of injury or some trouble with the bowels the valve at the junction of the appendix with the cecum finally opened up. Now fecal and septic matter would get into the little stump of the appendix, and as the end was open (or only covered by the loose muscles and fascia found in the iliac fossa) it burrowed in the direction of least resistance.

As the more resisting peritoneum covered the stump the pus fortunately did not break into the peritoneal cavity and thus the woman's life was saved. Her wonderful power of resistance carried her through all, although she was suffering virtually for twenty years with a suppurating appendix.

620 Woodward Avenue.

Therapeutics

OPHTHALMIA NEONATORUM

While the treatment of this serious inflammation is generally rightly referred to the oculist, it may occur in little patients whom it is impossible to bring under the specialist's care. Also, the prevention of this inflammation of the eye is of national importance, and should be understood and carried out by every practitioner who takes charge of obstetrical cases.

Dr. Julien A. Gehrung, New York (*New York State Journal of Medicine*, May, 1909), offers good advice for the prevention and treatment of this serious inflammation.

As soon as the child is born and after thoroughly cleansing the eyes, he advises the instillation of a drop of a 1 per cent. nitrate of silver solution. While Credé advised the use of a 2 per cent. solution, Gehrung thinks the 1 per cent. is of sufficient strength. After the child has been washed and dressed and the nurse's hands have been cleansed, he advises the instillation of another drop of the 1 per cent. solution into each eye, and this may be followed by a little physiologic saline solution or a drop of adrenalin chlorid solution (1 to 5,000). This "stops the pain and neutralizes the further action of the silver."

Gehrung believes that this prophylactic treatment is efficient and as satisfactory as can be obtained from any silver preparation.

If in spite of such prophylactic treatment (and he emphasizes the necessity of cleanliness as being next to godliness, both in the care of the child and in the nurse's care of her own hands) the conjunctivæ become inflamed, he advises the use of cold boric acid solution (if the cornea is not involved) and careful cleansing of the pockets of the conjunctivæ. The lid of the eye is gently raised, all pressure being avoided, and the tip of a soft rubber bulb syringe is inserted under the upper lid. Slowly and gently the eye is irrigated with the cold boric acid solution to wash out all purulent matter. "This should be done every fifteen minutes, or oftener if the discharge is profuse."

He next advises the instillation of a 4 per cent. solution of cocain and adrenalin chlorid (1 to 5,000) for its anesthetic effect and to cause contraction of the blood vessels.

The cornea should be carefully watched, and to inspect it properly, if necessary, a lid elevator should be used. If the cornea is involved, hot applications and atropin drops are indicated.

If but one eye is involved, the greatest care should be exercised to prevent infection of the other eye.

Once a day during the inflammation Gehrung applies a 1 per cent. nitrate of silver solution as follows: "Raise the lid slightly, and with a cotton swab saturated with the silver solution gently brush (raising the upper eyelid on the swab) the whole conjunctiva, both upper and lower, being careful to treat the cul-de-sacs thoroughly. Such treatment breaks up all adhesions, opens pockets of pus, and enables the medicament to reach all parts." If bleeding is caused, it does good rather than harm.

The point of the swab should be thoroughly protected by folding cotton over it so that it can not injure the membrane. To apply the above treatment it is not necessary to evert the swollen, painful lids; simple elevation of the upper lid by the retractor is sufficient.

If the disease is severe, Gehrung uses instillations, every one or two hours, of a strong, even up to 50 per cent., argyrol solution, but does not believe this alone is satisfactory, and reinforces it by one daily application of a 1 per cent. solution of nitrate of silver. He thinks the nitrate of silver kills the germs that cause the inflammation.

He believes that ice compresses are of value, applied from ten to twenty minutes every two hours, or, if possible, more frequently, "according to the vitality of the child," but if the cornea is involved, as above stated, hot applications must be used.

Proper nutrition, preferably mother's milk, and proper hygiene are important factors in aiding quick recovery from this serious inflammation.

SATURDAY, AUGUST 28, 1909

OLIVER WENDELL HOLMES

To-morrow, August 29, 1909, marks the hundredth anniversary of the birth of one whose name is probably more widely known than that of any other American physician. We refer to Oliver Wendell Holmes. The fact that the year 1809 saw the birth of four men of such varied genius as Gladstone, Tennyson, Darwin and Holmes has been frequently remarked. Dr. Holmes himself spoke of this circumstance in his "Hundred Days in Europe" in the following words: "It seems like an honor to have come into the world in such company, but it is more likely to provoke humility than vanity in a common mortal to find himself coeval with such illustrious personages"—a remark thoroughly characteristic of his breadth of spirit and not at all incompatible with the genial egotism appearing in many of his informal passages. The name of Dr. Holmes holds rather an unusual position in the annals of medicine and literature. There are great physicians who produced contributions to general literature, like Haller and Werlhof; and there are great writers who received a medical education, like Goldsmith and Keats; but the world has forgotten the literature of the former and the medicine of the latter. Dr. Holmes, however, belongs, with Sir Thomas Browne and "Rab's friend," to that small group who must be remembered both as devoted physicians and as lovable authors, because their writings are charged with personality, and the experience of their profession went to the upbuilding of that personality.

Moreover, while Dr. Holmes' lasting contributions to medicine are few, that he held a position of real influence in the medical thought of his day can not be doubted, as may be seen in the famous controversy concerning the contagiousness of puerperal fever. For forty years he was professor of anatomy at Harvard, keeping abreast of the progress of science to the end with all the enthusiasm of a young man; and yet he was the author of the exquisite lines of "The Chambered Nautilus." In this versatility, whose expression brought distinction in such widely varying fields, lies the most remarkable characteristic of his remarkable career.

It is perhaps of the genial "Autocrat" that we most often think when we hear the name of Oliver Wendell Holmes. The delightful humor and good sense of his philosophizings, his broad sympathy and charity toward all men, and his inexhaustible fund of anecdote and illustration have endeared him to us all, so that we turn back again and again to his "Breakfast Table" series to be cheered by his wit and to learn something of his fine charity.

The peculiar affection in which Dr. Holmes is held in medical circles is perhaps best explained by the fulness with which his life expressed the spirit that sang:

> A triple health to Friendship, Science, Art,
> From heads and hands that own a common heart!

THE FLY AND TYPHOID FEVER

The fly has from time immemorial been endured as a necessary scavenger. This it is, but a scavenger necessary only to those unaccustomed to reasonable and adequate cleanliness. While on the one hand the fly removes putrefying substances, on the other it distributes material at least as pathogenic—much tuberculous material, the virus of cholera, of tetanus, of trachoma, and of anthrax. It is certainly more than a coincidence that infant mortality is greatest in fly time. Milk is a very fair culture medium for bacteria, and amidst the uncleanliness obtaining in many families among the poor, it easily becomes contaminated with the excreta of flies and with the germs clinging to their feet. One fly was found thus to be the host for a hundred thousand fecal bacteria; "and it was on its way to the nearest milk pitcher." It is now generally agreed that the dysenteries and the diarrheas (except in the rare cases induced mechanically or nervously) are of microbic origin. Here the fly is surely implicated; especially since breast-fed infants almost never suffer the intestinal disorders which are deplorably frequent among the bottle-fed.

It is becoming manifest that the fly stands in a causative relation to typhoid fever. We have been accustomed to speak of typhoid as the autumnal fever. Counting back two months from the fall rise in typhoid mortality to the beginning of the fortnight's incubation, we come on the curve of prevalence of flies; the curve of high temperature most conducive to fly-breeding and activity; and also that of prevalence of diarrheal disease in both infant and adult. The time, then, when the fly is most active and numerous corresponds notably with the time when typhoid fever is contracted with unusual frequency. Many persons have come down with typhoid on returning to the city from their vacations, and tainted wells have generally been blamed; whereas, possibly in some cases the well has not been so blameworthy as the bluebottle.

The *Musca domestica* has not inaptly been termed the typhoid fly. Of course there are other means of contracting the disease than through this insect; but that it is a formidable agent can not be doubted. Its breeding-places are in the manure and refuse in and about stables; in the excrement of animals and human beings; in dust from dried urine and feces, and the discharges of "typhoid carriers;" in decaying vegetable matter, especially when congenial warmth and moisture coexist. Two hundred larvæ have been found in one inch of manure; ten days will suffice for the development of a brood; fifteen broods a season are possible; twelve flies surviving a winter may reproduce 40,000 during the following warm season. The fly's life is usually but a few weeks; but it may live dormant through the winter in closets and the warm parts of houses[1].

Felt[2] has found that this insect does not as a rule travel beyond three hundred to five hundred feet from its breeding-place; its habitat may indeed be close at hand—in spittoons, under the table, behind doors. It is, then, the part of wisdom to keep these insects from the sick-room, especially in contagious cases; to screen all doors and windows, especially in kitchen and dining-room; to cover or screen all food, particularly such as is uncooked, not only in homes, but also in hotels, provision stores and markets. Decaying material should not accumulate in or near a dwelling; fermentable refuse—bedding straw, waste paper, etc., which can not be burned or otherwise destroyed, should be covered with lime or kerosene oil; a modern sewage system, not leaking and not exposed, should be maintained; plumbing should be sanitary, filtration effective; kerosene should be poured into drains. Nuisances should be at once reported to health departments. Where there is no dirt and no filth there will be no flies. It is suggested[3] that the best and simplest fly-killer is a weak solution of formaldehyd in water (two drams to the pint); this should be put in saucers throughout the dwelling. Pyrethrum powder burned is also destructive of flies.

The typhoid bacillus may be carried from open drains, vaults and cesspools by flies, and then deposited by them on food and water; or the infection may be conveyed from open or box privies through underground drainage into wells, streams, small lakes and reservoirs visited by flies. Howard[4] would have large metal vessels used in rural districts; the excreta should be covered with earth, and the vessel should be emptied daily in a place where it is certain the drainage would not be dangerous. Manure should be put into tight pits or vaults without wire screens (which would be corroded by disinfectants); there should be an outer door from which the manure can be shoveled away. A barrel of chlorid of lime should be constantly at hand, from which each deposit of manure should be sprinkled.

Thus the breeding of flies may be prevented, but undoubtedly will not be until something like the same effort has been made to arouse public sentiment against the fly as against the mosquito. When by iteration and reiteration the chain of cause and effect that connects refuse, flies, and disease shall have become known to every one; when the housewife shall feel as much horror at finding a swarm of flies at her back door as she now feels at finding one in the parlor—then, perhaps, the day may come when scavenger flies will be as unknown in any self-respecting community as are now such scavenger dogs as those which constitute the street-cleaning force of Constantinople. Even if the extermination of the fly should not mean as much with relation to any one disease as the extermination of the anopheles has meant for malaria or the extinction of the calopus for yellow fever, in view of the number and variety of germs for which the fly is host, it is certain to mean an immense gain in general health.

THE TREATMENT OF NOCTURNAL ENURESIS WITH THYROID EXTRACT

Many causes have been assigned for the wetting of the bed at night by young and older children, but they have not led to any uniformly successful plan of treatment. In some instances, no doubt, the disorder may be traced to defective training, with the development of a vicious habit, but in many both provocative factor and remedial measure alike elude discovery. That the phenomenon may be due to some abnormality of internal secretion would appear to be shown by the interesting and instructive experience of Dr. Leonard Williams,[1] who records a series of 25 cases in which relief was afforded by the administration of small doses of thyroid extract. The suggestion was obtained from the case of a boy with nocturnal enuresis who instead of improving on removal of adenoids and tonsils became worse. Reasoning that the operation had deprived the child of a corrective internal secretion, Williams was led, on account of the intimate relations between the thyroid gland and the lymph glands, to try the therapeutic effect of thyroid extract. To use Dr. Williams' own words, "the effect was most dramatic." The enuresis ceased immediately and never recurred. Observations of a similar character had been previously made by a Belgian writer, Dr. Hertoghe, of Antwerp. It is important that the dose of thyroid extract employed be small—from ½ grain to 2½ grains thrice daily—as larger doses may defeat the purpose of the treatment, as was illustrated in one case in which enuresis previously absent developed in a boy to whom 2½ grains of thyroid extract were administered thrice daily for the correction of general debility following an attack of nephritis. The initial dose should be small, and it should be increased only if necessary, but no more should be administered than the minimum sufficient to effect the desired result. From the foregoing experiences it is argued that the thyroid secretion is a regulator of the action of the bladder and its sphincter, an excess being almost if not quite as deleterious as a deficiency.

SLEEPING SICKNESS

Sir Henry Hesketh Bell, Governor of the Uganda Protectorate, claims to have sleeping sickness under control in the region under his supervision. This feat was not accomplished, however, by any successful medical treatment. Professor Koch's work seems to have been unavailing, so far as finding any really curative method against the disease. The success was obtained by the most drastic measures. For several hundred miles along the shore of Lake Victoria, a strip two miles in width has been depopulated by order and the inhabitants removed inland. This was done by cooperation with the native chiefs, and the only people who remain within reach of the *Glossina* carrying the disease are the dwellers on a few islands from which it was not practicable to remove them. The mortality, which had ranged from 20,000 to 30,000 a year in the protectorate, fell during 1908 to less than 2,000, and the deaths occur now almost exclusively in the segregation camps; and it is believed that the new cases of infection are very few. The ultimate good result which is hoped for is that in a comparatively short time the disease will disappear from lack of sources of infection. Such a measure could only be carried out successfully with a docile population living under almost absolute authority, and constant vigilance will be required hereafter to hold the ground gained in the contest against the disease. It is not likely that so extensive a tract along the border of a navigable lake, the largest in Africa, can remain always unutilized, and the investigations into the cause and cure of sleeping sickness, the finding of the host of the protozoon, will have to be continued until some conclusive and valuable results are obtained. The sleeping sickness does not appear to exist along the shores of other African lakes, at least not to any such extent as has been the case in Uganda, which is an encouraging fact so far as the prospect of the complete success of Sir Henry Hesketh Bell's methods is concerned. Thus far certainly the outlook is encouraging.

ACUTE RHEUMATISM

Acute articular rheumatism or rheumatic fever was first described in the middle of the eighteenth century by Boerhaave, who was himself a sufferer from the disease. His description was subsequently elaborated by one of his pupils, van Swieten, in his commentaries on the aphorisms of his distinguished master. Sydenham was one of the earliest observers to recognize the affection, and he has given a most admirable account of it. For a long time the disorder was attributed to changes in the chemical constitution of the blood, but modern investigation appears to have demonstrated conclusively its bacterial origin. It is true that there are many forms of arthritis, whether affecting a single joint or many joints, and due to divers causes, but among these true rheumatism stands out as an acute specific, apparently self-limited disease, with well-defined clinical and pathologic characteristics. According to the view of Dr. Norman Moore,[1] who discusses the subject at considerable length in the Lumleian Lectures, the cardinal features of rheumatic fever are endocarditis and arthritis. The former he believes to be always present, in most instances causing permanent damage to one or more valves. He goes so far as to express the opinion that any disease attended with arthritis, but not with evidences of endocarditis, is not rheumatic fever. Accordingly, he proposes the term "heart fever" as the most appropriate designation for the disease. There may be in addition pericarditis or pleurisy. The distinguishing feature of the arthritis, as differentiated from other forms of joint inflammation, is the fact that complete recovery always ensues. The temperature curve is characterized by an initial rise, followed after a decline by occasional elevations, with intervals of normal temperature. Acute rheumatism is to be distinguished especially from ulcerative endocarditis and gonococcal arthritis. In cases of ulcerative endocarditis the joints usually escape, the temperature is high and oscillating, the disease is of protracted duration and recovery is rare. In cases of gonococcal arthritis evidences of endocarditis are generally wanting, while the lesions of the joints almost always leave permanent injury behind. Rheumatic fever, according to Moore, has an indefinite and variable duration, from two months to ten years or more, in accordance with the course of the attending endocarditis and the survival of the causative micro-organisms. Treatment consists mainly in protracted rest and the administration of some form of salicylic acid.

---

[1] Lancet, April 24, May 1, 8, 1909.

Medical News

CALIFORNIA

Personal.—Dr. and Mrs. Peter A. Jordan, San Jose, have returned from Europe.——Dr. Antoinette M. Bennette, San Bernardino, has been appointed resident physician and superintendent of nurses at the county hospital.——Dr. Thomas G. Hesser, Folsom, was operated on for appendicitis at Wentworth Hospital, Sacramento, July 28.

Sanatorium Dedicated.—The White Crusaders' Sanatorium for the Treatment of Patients Afflicted with Incipient Tuberculosis was dedicated July 16, at Alta. The site consists of 90 acres of wooded hillsides at an altitude of 3,600 feet, about one mile from Alta. The colony consists of eight buildings, grouped about the central sanatorium. In this building will be the dining-room, kitchen and general assembly room, and home of the resident physician. The sanatorium will accommodate thirty patients.

ILLINOIS

Chicago

Personal.—Dr. S. Josephine McCollum, recent medical superintendent and for ten years anesthetist at Mary Thompson Hospital, has withdrawn, entered private practice, and will make anesthetics a specialty.

KENTUCKY

Proclamation.—The State Board of Health has issued a proclamation setting forth that 39.1 per cent. of 119 samples of specimens of milk supplied to the city of Louisville examined are tubercular; showing that infectious and contagious diseases exist among cows producing milk for sale in Kentucky; announcing the existence of infectious and contagious diseases in the counties of the state, and giving rules for the prevention of the spread of these diseases and the protection of the health of the state. These rules provide that persons owning or controlling cows shall submit such cows to the tuberculin test; that no milk shall be sold in the state unless the cows producing same show a negative reaction to tuberculin; that all cows found to be infected with tuberculosis shall be destroyed at the cost of the owner; that all local boards through the state, the inspectors of the Bureau of Animal Industry of the

United States, and officers of the commonwealth shall cooperate with the officers of this board in this regard; that no cows such as are brought for immediate slaughter shall be allowed to enter the state unless they have shown negative reaction to tuberculin and have been inspected by the officers of the board.

MARYLAND

Hospital News.—The Polyclinic Dispensary will be opened in a short time on East Baltimore street. Dr. Leonard K. Hirshberg is chief of clinic and Drs. Newdigate M. Owensby, Claude A. Stonecipher, E. G. Linthicum, George W. DeHoff, Samuel Kahn, Henry H. Flood and Thomas H. Magness are his associates.——The Board of Estimates has appropriated $137,000 for improvements at Bayview Hospital. A wing will be erected to cost $87,000, making room for 150 additional beds, which will allow all patients to be in the hospital and empty the tunnel. This will also separate the insane from the indigent inmates.

Personal.—Dr. William K. White underwent an operation at University Hospital, August 5.——Dr. James M. H. Rowland has been elected chairman of the Democratic Advisory Committee of 120, which was appointed by the Democratic State Central Committee to manage the campaign next fall.——Dr. Percy Millard Dawson, associate professor of physiology in Johns Hopkins Medical School, has resigned.——Dr. Anton Dilger of the faculty of Heidelberg University is inspecting the hospitals of Baltimore.——Dr. Aristide Giampietro has been appointed physiologist in the Bureau of Plant Industries of the United States Department of Agriculture.

Baltimore

Personal.—Dr. Theodore Cooke, Jr., has been elected president of the National Prison Physician's Association which met recently in Seattle.——Dr. John Doyle, a resident physician at Mercy Hospital, was operated on for appendicitis in that institution, August 20.——Dr. William Henry Smith suffered a fracture of the fibula in a game of ball between the resident physicians and non-resident physicians of University Hospital, August 20.——Dr. Walter V. S. Levy, pathologist to University Hospital, has accepted a similar appointment to the Freedman's Hospital, Washington, D. C.——Dr. Matthew James McKinnon, of York, Pa., one of the oldest graduates of the University of Maryland, while on a visit to his daughter near Baltimore, was seized with a critical illness of the stomach.

MINNESOTA

New Hospital.—Drs. Archa E. Wilcox, Charles G. Weston and John Warren Little have had plans drawn for a hospital at Harriet and Franklin avenues, Minneapolis, to accommodate thirty-four patients.

Personal.—Dr. Edward W. Buckley, St. Paul, has been elected national physician of the Knights of Columbus.——Dr. Herbert O. Collins has been elected city physician of Minneapolis.——Dr. Wilcox has been appointed a member of the standing committee to take care of the Hopewell Hospital.

County Society Meeting.—The forty-first annual session of Wabasha County Medical Society was held at Wabasha, July 8, when Dr. Henry T. McGuigan, Mazeppa, was elected president; Dr. Joseph F. Bond, Wabasha, vice-president; Dr. William F. Wilson, Lake City, secretary and treasurer; Dr. Jesse A. Slocumb, Plainview, delegate to the state association; Dr. John P. Dougherty, Wabasha, alternate, and Dr. D. P. Dempsey, Kellogg, censor.

MONTANA

Smallpox Quarantine Abolished.—At a meeting of the State Board of Health, July 10, resolutions were adopted abolishing quarantine regulation of smallpox for the following reasons: Vaccination, properly performed and repeated at intervals, is an absolute preventative. The care of cases is a heavy expense on the counties. Properly vaccinated persons can not become a care on the counties.

Medical Board's Decision Affirmed.—A jury composed of Drs. Napoleon J. Salvail, Louis H. Fligman, Charles S. W. Thompson, all of Helena; McCabe, Oscar M. Lanstrum, Helena, and Max Barbour, heard an appeal in the District Court in the matter of the application of W. R. Smith, Roundup, to the State Board of Medical Examiners, for a certificate to practice. The jury returned a verdict sustaining the board and finding the defendant was not entitled to practice medicine in the state.

NEVADA

Hospital News.—At the meeting of the Goldfield Mine Owners' Association, Dr. Eugene A. Wheeler, formerly in charge of the Miners' Union Hospital, was selected to take charge of St. Mary's Hospital, succeeding Drs. D. Ashley Turner and Ora Burton Dunham.

New Laboratory.—Under the law creating a State Hygienic Laboratory at the University of Nevada and providing a bacteriologist for the diagnosis of infectious diseases for the physicians and health officers of the state and for research into the natural causes and control of such diseases, Dr. W. B. Mack has been appointed director of the laboratory.

Personal.—Dr. Francis C. Pache, Mina, was recently operated on in San Francisco for appendicitis.——Drs. Archibald L. Rice, Mack and John A. Lewis have been appointed members of the Board of Health of Reno.

NEW JERSEY

July Mortality.—During the month ended July 15, there were 2,606 deaths reported to the Bureau of Vital Statistics. It is noticeable that there is a decrease in the deaths from infantile diarrhea, measles, scarlet fever and diphtheria; cancer, infantile diarrhea, measles, scarlet fever and diphtheria, but an increase in cancer, cerebrospinal meningitis and nephritis.

Personal.—Dr. George H. Baker, Long Branch, is critically ill with cerebral hemorrhage.——Dr. Richard C. Barrington, Mount Holly, has succeeded Dr. J. W. Branin as a member and secretary of the State Board of Medical Examiners.——Dr. William F. Ridgway has succeeded Dr. J. Addison Joy as chief of the medical staff of the Atlantic City Hospital, and Dr. Samuel Barbash has been appointed chief of the dispensary work.

NEW YORK

New York City

Post-Graduate Hospital Acquires Property.—The New York Post-Graduate Hospital is to erect an annex to the hospital on property recently purchased by them for that purpose on Twentieth and Twenty-first streets.

Personal.—Dr. and Mrs. George L. Brodhead, Dr. and Mrs. Ferdinand C. Valentine, and Drs. Arthur S. Vosburgh, Charles S. Barnes, and Fred H. Albee have sailed for Europe.——Dr. Gordon Lindsay was recently assaulted and robbed of $200 on Twenty-sixth street and Second avenue.

OHIO

License Is Revoked.—The State Medical Board is said to have revoked the license of Dr. James M. Earnest, Alliance, June 30, and the license of Dr. J. G. Colton, Cleveland, July 6.

Election.—At the annual meeting of the Columbus Southside Physicians' Association, July 23, Dr. John Rauschkolb was elected president; Dr. Charles D. Dennis, vice-president; Dr. Harry Pershing, secretary, and Dr. Everett T. Tidd, treasurer.

Taken to Prison.—Dr. Norman M. Geer, Cleveland, said to have been five times indicted, thrice tried and twice convicted for performing illegal operations, who was refused motion for a new trial July 24, was taken to the State Penitentiary, Columbus, to serve his term of four years.

Illegal Practitioner Convicted.—Alba Dalka, Broken Branch, an Indian "herb doctor" of Tiffin, charged with the illegal practice of medicine, is said to have pleaded guilty and to have been sentenced to pay a fine of $25 and costs and to be imprisoned for sixty days in the county jail.

New Tuberculosis Hospitals.—A tuberculosis sanatorium to cost $50,000 is to be erected on the site purchased in McBeath Park, Lima, by Auglaize, Mercer, Van Wert and Allen counties, under the law recently passed by the legislature.——Preble and Montgomery counties have united in the acquisition of Brookside Sanatorium, which was opened August 2 with 14 patients.

Cincinnati

Personal.—Dr. Paul Gerhardt Wooley, professor of pathology in the University of Nebraska, has accepted the position of professor of pathology, and Dr. William B. Wherry, of the United States Public Health and Marine-Hospital Service, has accepted the position of assistant professor of bacteriology in the Ohio Miami Medical College, the Medical Department of the University of Cincinnati. Dr. Wooley will be pathologist and Dr. Wherry bacteriologist to the Cincinnati Hospital.

OKLAHOMA

Not in Good Standing.—The State Medical Board announced, July 15, that the Epworth Medical School of Oklahoma City is not in good standing, and that its diplomas will not be recognized in the future unless the requirements of the board are met.

Personal.—Dr. Robert E. Looney, Oklahoma City, has been appointed temporary city physician during the absence of Dr. William M. Hubbard.——Dr. William P. Fread, Enid, who sustained a fracture of the left leg in a runaway accident, has recovered.——Dr. Marcus H. Heldman, assistant city physician of Oklahoma City, has resigned.

Licenses Revoked.—The licenses of J. P. Norvell, Weleetka; James F. Lee, Eldorado; John Lindsay, Shady Point; Homer L. Wilson, Woodward, and W. A. Clark, Hitchcock, are said to have been revoked by the State Medical Board on the ground that they were not graduates of recognized medical schools, and were, therefore, illegally registered.

Hospital News.—The Duke and Rucks Sanatorium for Mental and Nervous Diseases, Guthrie, will hereafter be under the sole control of Dr. John W. Duke.——The Oklahoma Baptist Hospital, Muskogee, was formally opened for the reception of patients August 10. The institution is under the control of a board of trustees and is open to all reputable physicians.——The Ladies' Hospital Association, Muskogee, will begin immediately the erection of a forty-room hospital.——Shawnee recently voted $20,000 in bonds for the erection of a municpal hospital at that place.

PENNSYLVANIA

Personal.—Dr. Andrew S. Stayer, Altoona, has been reappointed surgeon-in-chief of the National Guard of Pennsylvania, with the rank of lieutenant-colonel.——A memorial tablet to Dr. Nathaniel Bedford, the first physician in Pittsburg, was placed on his tomb in Trinity Churchyard recently by the Daughters of the American Revolution.

Officers Elected.—At the annual meeting of the Lehigh Valley Medical Association, held at Delaware Water Gap, July 22, the following officers were elected: President, Dr. Obadiah H. Sproul, Flemington, N. J.; vice-presidents, Drs. Jonathan M. Wainwright, Scranton, and William E. Gregory, Stroudsburg; secretary, Dr. Clinton J. Kistler, Lehighton; treasurer, Dr. Albert A. Seem, Bangor.

Lodge Practice Condemned.—At the regular meeting of the Dauphin County Medical Society held in Harrisburg, August 17, a resolution was adopted requiring the expulsion of all members of the society who act as physicians for fraternal or beneficial orders under contract to treat members of such orders and their families at a fixed yearly rate, or who consult with physicians who engage in lodge or contract practice.

New Hospital Staff.—The new staff of St. Francis' Hospital, Pittsburg, is made up as follows: Medicine—Drs. Thomas G. Simonton, Ernest W. Willetts, Benson A. Cohoe and Howard G. Schleiter; surgery—Dr. Miller; [illegible] R. Huggins; diseases of children—Dr [illegible] Jr.; *x*-ray and skin diseases—Dr. Russell H. Boggs; ophthalmology—Dr. Edward A. Weisser; otology, rhinology and laryngology—Drs. Chevalier Q. Jackson and Edith T. Waldie; pathology—Dr. Ernest W. Willetts; and neurology—Dr. Thomas M. T. McKennan, Theodore Diller and W. Walker.

Medical Camp of Instruction.—The War Department designated the following members of the National Guard of Pennsylvania to attend the recent medical camp of instruction for officers at Antietam, Md.: Dr. Joseph K. Weaver, Norristown, colonel and surgeon-general; Drs. George H. Halberstadt, Pottsville, William J. Ashenfelter, Pottstown, Charles C. Wiley, Pittsburg, Morris F. Cawley, Allentown, Charles S. Turnbull, Philadelphia, William E. Keller, Scranton, Robert G. H. Hayes, Bellefonte, Benedict S. Ralston, Pittsburg, G. S. Crampton and Harlan Shoemaker, Philadelphia, majors and surgeons; Drs. P. Francis Gunster, Scranton, and M. Toland Sime, Philadelphia, captains and assistant surgeons; Drs. Edward M. Hand, Coraopolis, James F. Edwards, Pittsburg, Henry H. Doan, Philadelphia, Frederick A. Hartung, Pittsburg, Frederick O. Waage, Philadelphia, Robert S. McKee, Newhaven, William J. Crookston, Pittsburg, and John I. Robinson, State College, lieutenants and assistant surgeons.

Philadelphia

Hospital Buys Property.—The officials of Pennsylvania Hospital have purchased for $70,000 the property at 724 Spruce street. The building is occupied at present by the Women's Southern Homeopathic Hospital, which plans to erect a $150,000 new hospital at Broad and Fitzwater streets.

Wills Hospital Addition.—Plans have been prepared for the enlargement and improvement of Wills Eye Hospital. Beside interior changes to the present building, there will be an addition of three stories and basement, 80 by 32 feet.

Bequests.—By the will of the late Harry S. Henry, his entire estate, which is said to amount to $1,500,000, will revert on the death of the widow and his two sisters, to five local hospitals for establishment of beds for the treatment of white children.——The late Gustave Berntz bequeathed $500 to the German Hospital, and the late Elizabeth McGarvey $300 to the Presbyterian Home.

Personal.—Dr. David Braden Kyle has returned from Europe.——Dr. Andrew B. Kirkpatrick sailed for Europe August 14.——Dr. John H. Musser has gone to Europe to attend the International Medical Congress in Budapest. He is chairman of the American committee.——Drs. Luther C. Peter, Carle Lee Felt and H. Brooker Mills have resigned from the staff of the Northwestern General Hospital.——Dr. H. M. Goddard has returned from Europe.

Appeal for Epileptic Clinic.—A letter of appeal has been sent throughout the city asking for funds for the establishment of a clinic and an employment bureau for persons suffering with epilepsy. The clinic is to be known as the Letchworth Clinic for the Home Treatment of Epileptics. It is also aimed to start an employment bureau to be known as the Society for Securing of Suitable Employment for Epileptics, in order that persons suffering with that malady may be enabled to secure work without danger to themselves or their fellow-workmen.

RHODE ISLAND

Bequests.—By the will of Mrs. Henry G. Russell, Providence, $150,000 is devised to the Rhode Island Hospital, and $25,000 to Butler Hospital.——The will of Capt. Ira Winsor bequeaths $3,000 to the Rhode Island Hospital.

Personal.—Brown University has conferred the degree of D.Sc. on Dr. Charles V. Chapin, superintendent of public health of Providence.——Dr. John Howard Morgan, Westerly, has been elected a member of the board of censors of the Rhode Island Medicolegal Society.——Dr. William C. Monroe, health officer of Woonsocket, and trustee of the state sanatorium for tuberculosis of Wallum Lake, has started for Europe.——Dr. William R. Morse, Providence, has decided to enter the medical mission field in China.——Dr. Charles A. Sylvia has been appointed vice consul of Portugal at Providence

TENNESSEE

Medical School Closed.—The trustees of the University of the South decided that the medical department should be discontinued after commencement exercises, October 28. The hospital will continue in operation in charge of Dr. Allen Lawrence Lear.

Hospital Plans.—Plans for the Baptist Memorial Hospital, Memphis, are rapidly nearing completion and the fund for the hospital is rapidly growing.——The present home of the University of Tennessee, medical department, is to be converted into a hospital to be used for both schools, until the building proposed on College Hill can be erected.

Personal.—Drs. E. D. Watson and Walter S. Lawrence have been appointed Roentgenologists to the Memphis City Hospital.——Dr. Albert G. Kern has been elected physician of the Tennessee Deaf and Dumb School, Knoxville, vice Dr. John M. Boyd, deceased.——Dr. and Mrs. Winston T. Michie, Memphis, have sailed for Europe.——Dr. William L. Dudley, Nashville, has returned from abroad.

Medical Officers for Encampment.—The adjutant general has announced the following appointments of medical officers for state encampment: First regiment, encampment at Waverly, Captains R. B. Underwood and J. M. Troutt, Lieutenant Morris Hartman. Third regiment, encampment at Knoxville, Major James R. Nankivill and Captains A. G. Kyle, John Overton and S. L. Wadley. State rifle competition, Knoxville, Captains Larkin Smith and William E. Cooper.

VIRGINIA

Virginia Military Surgeons in Camp.—The following medical officers of the Virginia National Guard have been in attendance at the school of instruction at Antietam, Md.: Lieut.-Col. Junius F. Lynch, Norfolk; Major Lawrence T. Price, Richmond; Captains Adam T. Finch, Chase City; J. Fulmer Bright, Richmond; F. K. Travers Warrick, Richmond; Israel Brown, Norfolk; Harry B. Wall, Norfolk; and Collins.

WASHINGTON

New Hospital Being Built.—Dr. Emilion O. Houda, Centralia, is erecting a private hospital at that place with a capacity for fifteen beds.

Personal.—Dr. Alfred Ernest Braden, Tacoma, has been selected to fill the newly created position of city school physician of that place.

GENERAL NEWS AND COMMENT

Warning Concerning Agent.—Dr. William J. Thompson, Portage, Wis., writes that a man giving his name as George V. Smiles, or George Van Sands, and presenting a card of the American Claim Buyers' Union, 306 Hodges Building, Detroit —a firm which was not found at the address given—has been held to the Circuit Court at Portage for the alleged attempt to obtain money under false pretenses. Dr. Thompson asks us to announce this in THE JOURNAL. He says that the man is also wanted on two warrants at Janesville, Wis.

Federal Laboratories Will Furnish Plague Specimens to Colleges.—Surgeon-General Wyman announces that the Federal Laboratory of the Public Health and Marine-Hospital Service in San Francisco, Cal., will furnish to medical colleges and medical museums requesting them tissues illustrating the lesions of plague in guinea-pigs, and when practicable in other rodents, as well as stained slides showing the organism of plague as it is found in tissues from infected persons or rodents. By availing themselves of this offer, medical colleges should be able by means of safe specimens to demonstrate to their students the lesions of plague, and thus give practical instruction regarding a disease which is of great practical interest at the present time.

CANADA

Work of Tuberculosis Sanatorium.—The building for the Nova Scotia Sanatorium for Tuberculosis was completed in 1904, is situated on sixteen acres of land at Kentville, and cost $20,000. From June 1, 1904, to June 1, 1909, there have been admitted 298 patients to the institution. Of this number, 245 are available for classification, 73 being incipient cases, 93 advanced with favorable symptoms, and 79 far advanced. The conditions on discharge were as follows: 52 apparently cured, 123 improved, and 70 not improved. There were 60 per cent. of apparent cures in the incipient cases. Patients to this institution are admitted on the examination of either of two medical examiners residing in Halifax, the maintenance rate now being $5.00 per week. The institution is under the control of the government of Nova Scotia. The medical profession are advocating a resident physician.

Medical Societies Meet.—The annual meeting of the New Brunswick Medical Society was held in St. John, July 20 and 21, under the presidency of Dr. John R. McIntosh, St. John. The following officers were elected: President, Dr. H. A. Murray, Fredericton Junction; vice-presidents, Drs. Clinton T. Purdy, Moncton, and George G. Melvin, St. John; corresponding secretary, Dr. John S. Bentley, St. John; recording secretary, Dr. George G. Corbet, St. John, and treasurer, Dr. Daniel E. Berryman.——The fifty-sixth annual meeting of the Medical Society of Nova Scotia was held in Sidney, July 7 and 8, under the presidency of Dr. Arthur S. Kendall, Sidney. The subject of a laboratory and bureau of public health came up for discussion, on the report of the com[illegible] garding the communication of Dr. Arthur [illegible] ton, asking that a resolution be passed calling for a sub-laboratory for scientific and sociologic study of criminals, etc. The meeting unanimously adopted a resolution asking that the Dominion Government establish a central bureau of public health. A committee was appointed to report on affiliation with the Canadian Medical Association.

FOREIGN

Five Hundredth Anniversary of University of Leipsic.—The University of Leipsic celebrated, July 29, its quincentenary. It was founded as an offshoot of the Prague university and for centuries took the lead in medical science, and in some respects it still maintains its supremacy. In recent years the names of His, Wunderlich, Thiersch and Credé are familiar to all, and the organization of the medical profession in Germany was first effected there in the foundation of the *Aerztevereinsbund*. The organization that protects the economic interests of German physicians—the well known *Leipziger Verband*—owes its origin also to a Leipsic physician, Dr. H. Hartmann, who is still at its head. The celebration of the quincentenary was most impressive, fully sixty universities around the world having sent representatives, and thousands of students, alumni and guests gathered in the great coliseum built for the occasion. One feature of the celebration was the historic procession representing the various periods in the life of the university, the students in historic garb. An elaborate banquet was tendered by the state to one thousand guests. Among the honorary degrees conferred was one on ex-President Roosevelt, and four other Americans were thus honored: Professor Michelson, the physicist; Professors Loeb and Wilson, the biologists, and Professor Burgess, the publicist. Our current German exchanges contain numerous historical articles depicting the evolution of the medical faculty and medical science in general at the university. The old reputation of the university as one of the two or three recognized centers of scholarship in the world is still maintained by the present faculty, which includes Curschmann, Trendelenburg, Hering, Flechsig and Rabl. The university of Leipsic has the most handsomely endowed chair of the history of medicine in the world, the Puschmann endowment, of which K. Sudhoff is the incumbent. Leipsic is the center of the German book trade, and large numbers of scientific periodicals are published there.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Aug. 14, 1909.

Bursting of an Aneurism Declared to Be An Accident

A case which has just been decided, again shows the difficulties which the recent Workmen's Compensation Act involves and the extraordinary extent to which the term "accident" has been stretched. A workman had a large aortic aneurism which was liable to burst at any moment. While tightening a nut with a spanner, but not using more than ordinary force the aneurism ruptured and he fell dead. The case went into court and the judge held that death was the result of accident within the meaning of the act and gave compensation accordingly. The case was then taken to the court of appeals and the appeal was dismissed. The court held that the man, admittedly suffering from aneurism, had incurred a strain of a not extraordinary character during his work, which ruptured the aneurism. Therefore the case came within the law as laid down by recent decisions. But such cases have a result the very opposite of that intended by the framers of the act, which was intended to benefit workmen regardless of all other interests, and was passed in the present House of Commons by a government actuated by strong humanitarian motives and constantly importuned by a powerful and greatly increased labor party. Employers insure their workmen against the liabilities of the act. Insurance companies refuse to accept men with any physical defect or disease, however slight, which increases the chance of accident, and these are consequently refused employment. The result is that many men suffering from some slight defect which in no way interferes with their capacity for work are unable to obtain employment.

Pharmacists Object to Physicians Dispensing

It is a standing grievance with the medical profession that pharmacists not only dispense physicians' prescriptions, but do a large amount of what is termed "counter prescribing," generally for minor maladies, but sometimes inadvertently for serious ones. On the other hand the pharmacists consider it a grievance that the majority of the physicians in England dispense their own medicines. The only ones who do not are the consultants and the very small number of general practitioners whose clientèle is almost entirely wealthy. At the annual meeting of the British Pharmaceutical Conference, which has been held at Newcastle-on-Tyne, the president, Mr. J. F. Tocher, opened a discussion on the subject, "Should the Dispensing of Medical Prescriptions Be Confined to Pharmacists?" He said that the great grievance of pharmacists was that they were the only class specially educated and properly trained to prepare and dispense medicine, and as such, many of them got little if any employment in this kind of work because it was done by the medical profession. The total transference of the dispensing of prescriptions from physicians to pharmacists would in his opinion be advantageous to the medical man, the pharmacist and the public. He proposed to institute a joint standing committee, consisting of members of the British Pharmaceutical Conference and of the British Medical Association. Later if practicable, interested members of the public, including leaders of friendly societies, might be added. The duties of this committee would be to collect information on the actual practice with respect to dispensing and to the facilities for transference of the work to pharmacists in the cases in which the work was done by physicians. A number of local physicians took part in the discussion and a resolution to the above effect was carried. A discussion on this subject took place a few years ago in the columns of the *Lancet* and it was shown that it would be a great advantage in many ways if physicians were relieved of the work of dispensing. The profession would gain in dignity and would have more time to devote to its proper work, the treatment of the sick, and also more leisure. But in poor and club practice there would be a marked increase of expense which it would be difficult to transfer to the patients. It is very unlikely that the present system will be abolished. Moreover, the claim of pharmacists that they are the only persons trained to dispense medicines is not correct. Every medical student has now to go through a course in pharmacy.

Carbon Tetrachlorid for Shampooing

In a previous letter (The Journal, July 31, p. 392) I reported the case of a young woman who died while her hair was being shampooed with tetrachlorid of carbon. The view that the shampoo is not quite so harmless as has been thought is confirmed by an article contributed to the *Lancet* of August 7 by Dr. A. D. Waller, director of the physiologic laboratory of the University of London, with an added note by V. H. Veley, D.Sc., F.R.S., a distinguished chemist. Dr. Waller has investigated the toxicity of various drugs by means of their action on isolated muscle. He finds that the toxicity of a molecule of chloroform is 100 times greater than that of a molecule of alcohol. Carbon tetrachlorid he finds more toxic than chloroform and the incriminated hair shampoo (which contains in addition, impurities, of which the most important is carbon bisulphid to the extent of 1.5 per cent.) still more toxic. Dr. Veley considers that the bisulphid is so intensely poisonous that even in this small percentage it increases the toxicity of the shampoo. He further points out that as carbon tetrachlorid is very heavy (5.3 times as heavy as air), notwithstanding any fanning the vapor, which is considerably more toxic than chloroform, must fall over the face of the person shampooed. He thinks that legislation is called for to prohibit the use of carbon tetrachlorid in hair-dressing.

Munificent Bequest for Cancer Patients

If the cancer problem is not solved it will not be for want of funds. The latest sum to be devoted to the disease is the munificent one of $1,250,000, which was left by the late Mr. Harry Barnato for the purpose of founding some charity in commemoration of his brother, Mr. Barney Barnato, and his nephew, Mr. Woolf Joel. After considering many schemes the trustees have decided to apply the money to the building and endowment of an institution for the reception of cancer patients. To increase the potentialities of the bequest the institution will be administered in connection with the Middlesex Hospital, the only general hospital in London which has special wards for cancer patients and special laboratories devoted to investigation of the disease. A site has been acquired adjoining the hospital's cancer wards. The advantages of the trustees cooperating with the hospital are considerable. The cost of organizing the new undertaking will be greatly diminished and they will have the guidance—administrative and medical—of those whose experience of the disease is exceptional. The trustees intend to devote $10,000 to the erection of research laboratories of a character calculated to induce men of the highest skill to work in them.

A Woman Member of the Royal College of Physicians

For the first time in its history the Royal College of Physicians has admitted to its membership a woman, Miss Ivy E. Woodward, M.D. Lond. The ordinary qualifications granted by the college is the license which is associated with the familiar letters L.R.C.P., but the distinction now obtained is the M.R.C.P., the highest diploma obtainable by examination at the college, which is possessed by, and is the hall-mark of, consulting physicians.

PARIS LETTER

(From Our Regular Correspondent)

Paris, Aug. 11, 1909.

The Bureaus of Hygiene

According to the law of 1902, each city of more than 20,000 inhabitants is to have a bureau of hygiene with authority to take sanitary measures and to oversee their execution throughout the commune. But sixteen of the most important communes of the Department of the Seine have protested against the change in organization required by the law, both on account of the expense, and also because they are obliged to put a physician at the head of each bureau. The mayors of these communes say that they can not dismiss the non-medical officials who have hitherto directed the bureaus. The prefect of police thought that he might compromise by merely exacting that each director who did not have a medical degree should be assisted by a physician. The Council on Hygiene has just refused to sanction a compromise by which physicians should work in bureaus of hygiene under the orders of non-medical directors

Increase in Medical Fees

The medical society of the fourth ward (arrondissement) of Paris having recently taken up the question of the increase of medical fees (The Journal, July 10, 1909, p. 126), a mixed commission, composed of representatives of the medical societies of the Department of the Seine, of Paris and of the wards of Paris was formed to study this question. This commission has just decided that it is necessary (1) to increase medical fees by at least a third over current rates for ordinary visits and consultations, each ward making the minimum rates that are suitable for it; (2) to ask higher rates for urgent, evening and Sunday visits; and (3) to establish a minimum scale for the special procedures of current practice.

The Congress of Alienists and Neurologists

The nineteenth Congress of Alienists and Neurologists of France and of French-speaking countries has just been held at Nantes, August 2 to 8. Among the questions discussed, which I have already mentioned in a preceding letter (The Journal, June 19, 1909, lii, 2006) that of insanity in the army from the clinical and medicolegal point of view, assumed special importance. The ministry of war had sent a special delegate, Dr. Simonin, professor at the school of military hygiene at Val-de-Grace. It was the first time that the military administration had been represented at the Congress of Alienists and Neurologists. Numerous magistrates were also present. The president of the congress, Dr. Vallon, chief physician of the Ste. Anne Asylum at Paris, congratulated himself on the increasing interest among legists in the problems of medicolegal psychiatry.

According to the report of Dr. Granjux of Paris, there are annually invalided 0.6 per thousand of the effective military force for "mental alienation, idiocy and general paralysis." In this reckoning those who are invalided for hysteria, epilepsy, neurasthenia and alcoholism are not included; if the latter are added the percentage is 1.8 per thousand; and even this is far too low to represent the actual proportion of the insane, for insanity is often not recognized. The French army, however, is not in a comparatively bad state in this respect. The number of the insane is, it is true, somewhat less in the German army, but it is even a little larger in other armies having general military service, and very much larger in the countries where military service is not general, such as Great Britain, Belgium, etc.

After the discussion of the reports of Dr. Granjux, and of Dr. Rayneau of Orleans, the congress passed resolutions looking toward the strengthening of the army and navy medical corps on the side of psychiatry and the collection of better statistics on insanity.

The congress will meet in 1910 in Brussels and Liège under the presidency of Drs. Crocq of Brussels and Klippel of Paris. The subjects of discussion will be: (1) sleeping sickness and narcolepsy; (2) the classification of cutaneous lesions in nervous maladies; (3) alcoholism from the criminologic point of view.

The French Association for Advancement of Science

The thirty-eighth session of the French Association for the Advancement of Science was held August 2 to 7 at Lille under the presidency of Professor Landouzy, dean of the College of Medicine of Paris. M. Henri Poincaré of the French Academy and the Academy of Sciences was awarded the large gold medal of the association, which last year was awarded to the illustrious English savant, Sir William Ramsay.

The section of medicine, presided over by Professor H. Roger of Paris, discussed questions of practical interest, such as the new methods of diagnosis and treatment of tuberculosis, recent contributions to the subject of epidemic cerebrospinal meningitis, etc.

In the section of medical electricity, which brought together a great many members, a large place was naturally given to radiography. A paper by Dr. A. Imbert, professor of medical physics at the College of Medicine of Montpellier, on errors of interpretation in radiography and a paper on the same subject presented by Drs. A. Mouchet and Lamy of Paris, aroused great discussion. A great number of papers were devoted to the treatment of arteriosclerosis by high frequency currents. Dr. Lejars, professor *agrégé* at the College of Medicine of Paris, presented a question of great practical interest, namely, the indications for use of electricity in ileus.

Next year the association will meet at Toulouse under the presidency of Dr. C.-M. Gariel, professor of medical physics at the College of Medicine of Paris.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Aug. 4, 1909.

The Incidence of Infectious Diseases in Prussia

According to the ministerial report on the health of Prussia in 1907, which I have already mentioned, there was a considerable increase in the mortality from influenza. There died of influenza in Prussia 5,512, that is, 0.145 per thousand living and 0.81 per hundred deaths. The largest previous influenza mortality occurred in 1892, during the great influenza pandemic, when about 16,000 or 0.523 per thousand living died in Prussia. The three winter months, January, February and March, in 1907, especially February, had the highest mortality; September the lowest. The deaths according to ages were as follows: Infants, 351; children 1 to 15 years old, 354; between the ages of 15 and 60, 1,395, and over 60, 3,412. The number of cases of typhoid continually decreases in Prussia, dropping from 4,410 cases in 1901 to only 2,168 in 1907. The typhoid mortality is declining still more rapidly, from 0.264 per thousand living in 1887 to only 0.057 in 1907. The largest number of deaths according to age occurs between 30 and 40; the highest relative mortality between the ages of 20 and 25. The morbidity was highest during the summer months. In most cases the diagnosis was confirmed bacteriologically. The government laboratories have also in many cases discovered bacillus-carriers; for example, in a village parsonage in which cases of typhoid continually occurred, while the rest of the village remained free, it was discovered that the pastor's mother had typhoid bacilli in her stools; she had had a severe attack of typhoid thirty-seven years before. Among the customers of a city milkdealer cases of typhoid continually occurred, and a maidservant in the village from which the dealer obtained his milk was discovered to be a bacillus-carrier. The spread of typhoid generally occurred through conveyance from person to person; also through infected water, through milk from dairies, and through other foodstuffs; a few times through the washing of the clothes of a typhoid patient. There were 57 cases of paratyphoid reported, 7 of spotted fever, and 3 of relapsing fever. There were 185 deaths from dysentery. Malaria seldom occurs. Trachoma is still prevalent, especially in the east of our country. In the district of Königsberg there were 1,872 trachomatous school children reported in 1907; in the district of Dantzig, 2,000; in the district of Posen, 3,800. There were 2,591 cases of epidemic cerebrospinal meningitis with 1,613 deaths, or 62.47 per cent.; the largest relative number of cases occurred in April. Only 142 cases of smallpox were reported during the whole year. There were 338 cases of traumatic tetanus, the mortality being about 75 per cent. The patients treated for gonorrhea in the general hospitals numbered 20,000, and for syphilis and soft chancre, 22,000. There were 3,771 mothers who died of puerperal fever, or 2.942 per thousand parturients. The diphtheria mortality has continued to decline during the last decade; in 1898, 18,147, or 0.556 per thousand living, died; in 1907, only 9,307 died; that is, 0.246 per thousand living.

Death of Professor Runge

A few weeks after the death of Pfannenstiel, German gynecology suffered another heavy loss in the death of the director of the Göttingen gynecologic clinic, Prof. M. Runge. He died in Berlin, aged 59, following an operation for kidney disease. Runge began his academic career as assistant to Leyden in Strasburg, his gynecologic work as assistant to Gusserow in Berlin. Before his professorship at Göttingen, in 1883, he was called to Dorpat as ordinarius, and in 1888 he, like all the other German professors, left the Russianized and ruined university. Aside from his numerous scientific works, Runge was best known by his text-books on obstetrics and gynecology, and as the author of the official manual for midwives now in use in Prussia.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, Aug. 9, 1909.

The Health of Potters

A series of investigations into the health of certain classes of the population has been instituted by Chyzer and reported to the board of health. The occupation of the pottery makers requires the presence of lead in the inhabited places, and as in this country there are many potteries in dwelling-houses where even young children are employed, the danger to health is great. Thus in some instances the dust collected from these houses contained up to 14 per cent. of lead. Constant human lead-poisoning is often observed among them; the household animals also fall victims to the occupation of their masters. Fowls and ducks can not thrive in the vicinity of potteries; dogs and swine are killed by drinking water polluted with the lead-containing waste of the process, and cats are especially susceptible. The latter animals often show colic, loss of flesh and nervous disturbances, with terminal paralysis. As a rule, all household potters are attacked at least once before having completed their third year at this occupation, and many patients had been five or six times in the hospital. It is not yet possible to forbid the factories in dwelling-houses, as many people would be thrown out of work, especially in this country; and the regulations of the board of health dealing with these conditions are in force only in the towns. The death rate of the potters is high: Of 3,010 men examined, only 265 were apparently healthy, and only 16 were over 60 years old. The average age at death is only 41 years! The conclusions arrived at by the investigations point to the necessity of prevention of all kinds of pottery work except in properly conducted large factories.

The Arrangements for Infectious Corpses in the Vienna Cemetery

A new morgue has been opened recently in Vienna in the general cemetery for the purpose of dealing with persons dead from infectious diseases. The corpses are placed in the lying-in-state hall, which is separated by glass walls from the general waiting-hall for the friends and relations of the deceased. Special care is taken to prevent the possibility of transmission of disease during the burial ceremony. Once the body is brought to the cemetery, nobody touches it except the two to four men necessary to bring it to the grave. Even the priest must fulfill the necessary rites while separated from the body by a glass screen. The corpse is brought in a disinfected coffin, is covered with phenol or lysol, and the friends may follow only at a certain distance. The bearers must, after each funeral, change their clothes, which are at once disinfected by steam; they themselves must take a hot bath at once. The bathing rooms divide the infected area of the building from the non-infected one. Doctors, servants, bearers—all persons who have had anything to do with the corpse in the house—must pass the same ordeal of bath and disinfection of clothes. Their clothes are handed to them only after their baths. The refuse and water used in the morgue are carried away by a special system of drainage and thoroughly disinfected. A dissecting-room, together with a laboratory, is in connection with the morgue, and all work is done here under the strictest precautions. For especially dangerous corpses, there are three isolation cells, capable of holding three bodies at a time, so that a more effective disinfection is possible. The cost of the institute amounted to only $60,000, and the current expenses amount to about $70 per funeral.

The Weather and the Health

The unusual climatic conditions this summer have had a marked influence on the general health. According to the monthly returns of the bureau of health the number of affections of the alimentary canal among children is unusually small compared with the number of cases of infectious diseases owing to the protracted period of rain lasting now, with some slight interruptions of from three to five days of fine weather for more than twelve weeks. Summer diarrhea, cholera infantum and other summer affections are nearly absent. Perhaps the freedom from cholera, in spite of its ravages in the neighboring districts of Russia, is also partly due to the excess of rain. Another very welcome feature of this summer, in itself perhaps no less responsible for the good health of the public, is the complete absence of flies and other insects observed by the farmers. Diseases of the respiratory organs, as well as rheumatic conditions, have been and still are very numerous, though mortality is low. On the whole, central Europe, to which this country belongs, has had the privilege of enjoying a regular oceanic climate similar to that of Ireland.

The Conflict Between Dental Surgeons and Dentists

In this country there are two kinds of dentists, the *Zahnärzte*, surgeon-dentists with the diploma of M.D., and the *Zahntechniker*, or dentists without university or hospital diplomas. The latter were until recently only assistants of the surgeon-dentists, doing chiefly the technical dentistry, prosthetic appliances, putting in artificial teeth and crowning partly destroyed teeth. But about a dozen years ago these assistants obtained permission to practice this prosthetic dentistry if controlled by a qualified surgeon, and since that time they have always been endeavoring to shake off the control and become independent. Indeed, they even try to get the whole of dentistry into their own hands and leave to the surgeon-dentist nothing but the filling of the carious teeth, or the extraction of whole teeth, while the extraction of stumps necessary in the adaptation of the mouth before use of artificial teeth they claim for themselves. The demands of the technical dentists mean nothing else but the overthrow of the law prohibiting quackery. The medical profession as a whole has endorsed a protest addressed by the medical council of Vienna to the Minister of the Interior. A compromise has been suggested by the other party, all the present dentists possessed of diplomas or not, to be allowed to practice in the human mouth, but in future no independent technical dentists to be permitted. This being refused by the medical profession, the technical dentists have changed their tactics and cry for a clear division of rights, surgical procedures to belong to the surgeons, artificial dentistry to the technical dentists. The acceptance of this platform would mean the ruin of the dental surgeons, for hardly ten men could make a living out of extraction and stopping of diseased teeth only. There are over 400 dental surgeons in Vienna alone, while there are in all Austria about double the number of technical dentists. There is reason to hope that the medical point of view, being identified with the interests of the public health, will prove the stronger of the two.

The Jubilee Hospital in Vienna

The municipality of Vienna proposes to spend $2,250,000 in the erection of a hospital with 1,000 beds, intended to commemorate the jubilee of the Emperor Francis Joseph. The directors and heads of the departments will not belong to the Vienna University. In October the work will be commenced, and it is expected to finish it in eighteen months. The plans provide for open air pavilions and spacious corridors for children. Details of the hospital, which will be the most up-to-date institution of its kind, will be forthcoming in a short time.

Pharmacology

BUCHANAN CANCER REMEDY

A correspondent submitted for analysis a "cancer paste" that had been manufactured and sold by the Buchanan Medical Co. of New York City. The only information available concerning the composition of the paste was that contained in a booklet formerly published by the manufacturer, in which it is stated:

"Chlorid of Chromium (ozonized; the cancer antidote). The liquid chlorid of chromium is added to pulverized bloodroot, or some other inert powder; is made into a paste of the consistency of tar . . ."

ANALYSIS

The sample was submitted to the Association laboratory, which reported as follows:

"The sample of Buchanan's Cancer Cure was a dark, brownish-red, pasty mass of about the consistency of tar. Its odor was not characteristic. Examination showed that chromium salts were not present. The active ingredient was found to be zinc chlorid. With this was mixed a finely ground vegetable powder and some mucilaginous substance. Glycerin, sugar, alkaloids, resins and fats were not found. The vegetable tissue possessed the general structures of rhizomes and in some characters resembled bloodroot, but could not be identified positively. There was considerable starch present, but its identity could not be made out, since the structure of the starch grains had been destroyed, probably by the zinc chlorid. A red coloring matter was present. Further than a quantitative determination of zinc chlorid, an exhaustive chemical examination was not undertaken, although tests were made for a considerable number of substances which the nature of the remedy suggested.[1] The analytical results are given herewith:

Anhydrous zinc chlorid............	46.3 per cent.
Vegetable tissue, dry...............	9.2 per cent.
Mucilaginous matter	12.2 per cent.
Moisture	19.1 per cent.
Undetermined (starch, loss, etc.)....	13.2 per cent."

Zinc chlorid mixed with an absorbent, such as flour, starch, powdered *galangal*, powdered althea, gypsum, etc., has been employed in the treatment of cancer for many years. The Buchanan remedy, therefore, evidently contains nothing new. It belongs to that great army of "wonderful new discoveries" which examination usually shows to be well-known remedies. The statement that the cancer antidote is "chlorid of chromium ozonized" is not only false but meaningless, no such product being known. It is evidently intended to mislead the unwary physician by the use of the term "ozonized."

THE AMERICAN COLLEGE OF MECHANO-THERAPY

"Manual Manipulation" and "Curative Mechanics" Taught by Mail

In the realm of the new "drugless" quackery probably no field has been more thoroughly worked than that of "manipulation." The absence of laws in many states and the inadequacy of such laws as do exist makes the "treatment" of disease by mechanical means a veritable gold mine for the unscrupulous and incompetent. The rise of osteopathy and its latest freak offshoot—kiropractic—is but one illustration of what has been done in the way of commercializing manual manipulation as a therapeutic agent.

In his "Great American Fraud" series Samuel Hopkins Adams calls attention to the absurdity of the proposition put forward by numerous quacks that it is possible to treat diseases by correspondence. As Mr. Adams says, it is "like mending chimneys by mail." On a par with this is the teaching of "manual manipulation" by correspondence. This feat is accomplished (?) by an institution calling itself the "American College of Mechano-Therapy" having its headquarters in Chicago.

The advertisements of this concern put the "science of mechano-therapy" as taught by it on a frankly commercial basis. The important and much-emphasized point is that by studying mechano-therapy you can "earn from $3,000 to $5,000 a year."

WHAT IS A "MECHANO-THERAPIST?"

The individual who, attracted by this get-rich-quick proposition, is anxious to learn something about the general principles of the cult, is told:

> "His [the mechano-therapist] medicines . . . . . are not drugs but scientific combinations of food, circumstance, idea, water and motion."

After mentally digesting this somewhat abstruse proposition, descriptive of the fundamental principles of mechano-therapy, the reader learns further, that:

> "His instruments are not knives and saws, but his own deft hands and the vital processes of the body itself, the circulation, respiration, secretion, etc., which he manipulates as he sees fit and his judgment dictates."

In other words the graduate of the American College of Mechano-Therapy "manipulates as he sees fit" his patient's "secretion" by "scientific combinations of food, circumstance, idea, water and motion." It would surely be hard to find a more meaningless jargon of words outside of Mrs. Eddy's "Science and Health."

The dean of this "college" is W. C. Schulz, M.D., who, we are told, "has had a thorough European training, and so *combines all the learning of the great schools of the world.*" [Italics ours.—Ed.] The subjects taught at this institution of learning are, according to the catalogue, the following:

> "Anatomy, Physiology, Diagnosis, Hygiene, Dietetics, Hydrotherapy, Manual Manipulation, Swedish Movements, Vibration, Oscillation, Mechanics (curative), Suggestive Therapeutics . . . Ethics, Establishment, Promotion and Business Methods."

---

[1] Details of Analysis.—Owing to the small quantity of sample submitted, duplicate determinations could not be made.

Alcohol-insoluble: A portion was dissolved in alcohol so far as possible, filtered, dried and weighed; 1.6578 gm. gave 0.3557 alcohol-insoluble residue, or 21.4 per cent.

Zinc: The alcohol-insoluble portion was washed, dissolved in hydrochloric acid, so far as possible, the filtrate, added to the alcohol-soluble portion, the mixture evaporated to small bulk, and the zinc precipitated as zinc ammonium phosphate. (Olsen, "Quant. Chem. Anal.," 1904, pp. 82 to 84.) The precipitate was dissolved in hydrochloric acid, re-precipitated, dried, ignited and weighed as zinc pyrophosphate. 1.0790 gm. gave 0.5599 gm. zinc pyrophosphate, equivalent to 46.3 per cent. anhydrous zinc chlorid.

Moisture: This was determined approximately by drying over concentrated sulphuric acid; 1.0790 gm. gave a loss of 0.2063 gm., or 19.1 per cent.

Vegetable Tissue (water-insoluble portion): This was determined by dissolving a sample as completely as possible in distilled water, filtering and drying the residue at 98C.; 3.264 gm. gave 0.3011 gm. residue, or 9.23 per cent.

Mucilaginous Matter: An approximate value for the mucilaginous substances and soluble starch was obtained by subtracting the portion insoluble in water (vegetable tissue) from that insoluble in alcohol (vegetable tissue and mucilaginous substances). 21.45 per cent.—9.22 per cent.=12.23 per cent.

In addition to these numerous subjects, "Osteopathy" is thrown in for good measure; and all this is taught by correspondence! Apparently there is no limit to human credulity when cupidity beckons. In referring to the time required to complete the "course" and thus receive the diploma, which is "handsomely executed on art parchment," we are told:

> "In six months you can begin practicing mechano-therapy."

Of course the acquirement of the *tactus eruditus* is all-essential, "but it is no more difficult than learning to ride a bicycle." And incidentally that suggests the commercial possibilities of teaching bicycle riding or even equestrianism by mail!

THE "BUSINESS SIDE"

In addition to the various subjects from anatomy to suggestive therapeutics that are taught by this "college" the curriculum includes "The Business Side of Mechano-Therapy." This *important* subject deals with such problems as:

> "How to approach a Patient."
> "How to get the Fees at once."
> "The Business *talk* that will make the Patient willing to pay the fee."
> "How to handle the Question of the size of a Fee."
> "Real Money Talk."
> "Always get Cash down."

The "business side," too, is particularly emphasized in the advertisements of the college:

> "Opportunities to make money in Mechano-Therapy are everywhere. You need not leave home to make your fortune."
> " . . . . we guarantee success . . . . . . "
> "We fit you in a few months so you may become successful and earn from $3,000 to $5,000 a year."
> "Unlimited income to graduates."
> "We know of no other calling . . . which promises the same financial returns that Mechano-Therapy does."

Such is the bait, which, judging from the amount spent in advertising, is so productive of results in catching the ignorant and avaricious.

The "instructor" in "business methods" is one S. J. Tinthoff, who also is treasurer of the "college." We learn from the prospectus that as instructor, he "is eminently well qualified for this position." In fact:

> "His knowledge of the proper methods a physician, specialist or Mechano-Therapist may pursue in order to build up a large practice, is perhaps unsurpassed by that of any other man in the United States."

We are told, too, that F. S. Tinthoff, brother of S. J. Tinthoff, and "Director of the Correspondent Department, is also a trained business man and expert correspondence instructor." We understand that F. S. and S. J. Tinthoff operate the "Aurum Company," which does a mail-order business in "Vestro," which is modestly claimed to be "the only true Bust Developer on the market to-day." If we are not mistaken, too, F. S. Tinthoff was president and treasurer of the now defunct "Physician's Institute" of Chicago. The question arises: Does an experience in operating a "physician's institute" and filling mail-orders for the "only reliable bust developer" qualify a man for the position of "instructor" in a correspondence "college of Mechano-Therapy?"

LEGAL STATUS OF MECHANO-THERAPY

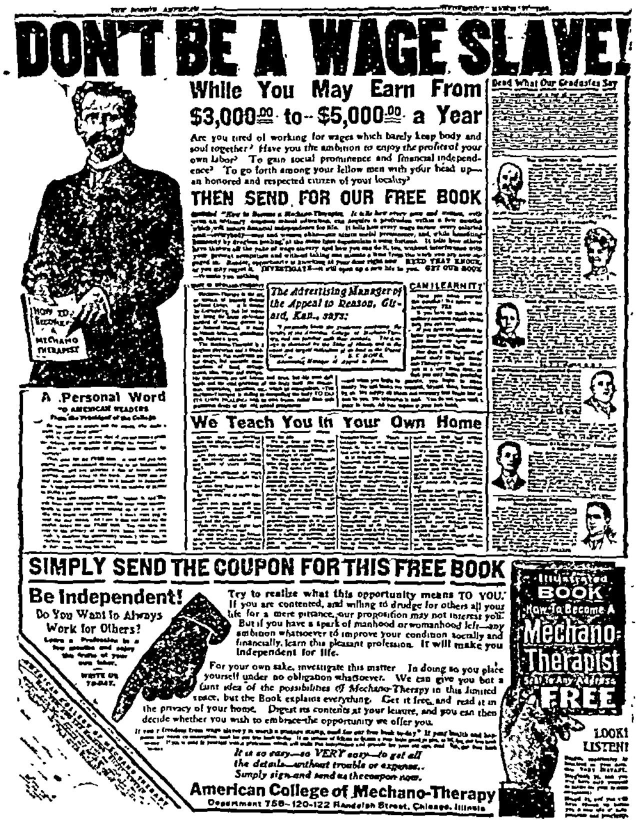
The American College of Mechano-Therapy advertises: "We Teach You How to Treat Disease Without Drugs." A prospective student who wished to know what legal restrictions there might be to the practice of this method of "treating" disease, wrote as follows: "If I should take your course and receive a diploma could I practice Mechano-Therapy in *any* of the states? I understand that the different states have different laws regarding the practice of medicine and I would like to know if there are any restrictions in regard to Mechano-Therapy?"

The reply he received may well be pondered over by those who believe that medical practice acts exist for the benefit of the public:

> Dear Friend:—There are no laws on the statute books regarding Mechano-Therapy. In Illinois for instance, there is the so-called "*Drugless Healing Act*" applying to all such methods as Mechano-Therapy, Osteopathy, etc. Some of our graduates have qualified under this law by examination, while *others carry on their work under the advice and consent of a friendly M.D. We recommend the latter method* [Italics ours.—Ed.] until such time as Mechano-Therapy is regulated by legislative enactment in the various states.
>
> Yours truly,
> American College of Mechano-Therapy,
> W. C. Schultze, M.D.

METHOD OF INTERESTING "STUDENTS"

The individual who writes to this college for information receives a three-page letter and a "prospectus" The latter is *entitled*, "*How to Become a Mechano-Therapist*," and the first page is taken up with a full-page picture of the "home of the American College of Mechano-Therapy." This "home" is pictured as a nine-story building, across the top of which appears in large letters, the legend: "American College of Mechano-Therapy." The natural inference to one not conversant with the facts would be that the "college" occupied the entire building. In reality, however, it occupies some rooms on the sixth floor of the building in which it is located, and the building carries no such legend as is shown in the picture.



DON'T BE A WAGE SLAVE!

While You May Earn From $3,000.00 to $5,000.00 a Year

Are you tired of working for wages which barely keep body and soul together? Have you the ambition to enjoy the profits of your own labor? To gain social prominence and financial independence? To go forth among your fellow men with your head up—an honored and respected citizen of your locality?

Be Independent!
Do You Want to Always Work for Others?

WRITE US TO-DAY.

Try to realize what this opportunity means TO YOU. If you are contented, and willing to drudge for others all your life for a mere pittance, our proposition may not interest you. But if you have a spark of manhood or womanhood left—any ambition whatsoever to improve your condition socially and financially, learn this pleasant profession. It will make you independent for life.

For your own sake, investigate this matter. In doing so you place yourself under no obligation whatsoever. We can give you but a faint idea of the possibilities of Mechano-Therapy in this limited space, but the Book explains everything. Get it free, and read it in the privacy of your home. Digest its contents at your leisure, and you can then decide whether you wish to embrace the opportunity we offer you.

It is so easy—so VERY easy—to get all the details—without trouble or expense. Simply sign and send us the coupon now.

VARIABLE TUITION RATES

The form letter, after expatiating on the virtues and money-making possibilities of the "course" winds up by calling attention to the fact that the tuition is $100 cash "for the complete course." The tuition rates, however, seem to vary. One person who inquired about the course was told in the first letter that it cost $100; in the second letter he was told that "*we expect* shortly to advance our fees to $200"—but they would still accept this particular individual at the $100 rate; in the fourth letter he was told that the advance *had been made* "and our present terms are $200 cash," but as a special proposition he would be accepted "at the old special reduced rate;" in the *fifth* letter he was offered the "complete course" for $60, but the "college" insisted that he *must* "hold this special reduced price strictly confidential." As a (presumably) final "confidential price" he was offered the "regular $100 correspondence course in Mechano-Therapy for only $25 cash."

Another individual was offered the course for $50—and this, too, within a few days of the time that the first person received notice that the fees had been "advanced" to $200. Other persons have been offered a 50 per cent. discount ($50 cash) with the first letter. It should be said that all the "enrollment blanks" which we have seen—and they are many—give the cost of the course as $100.

The extensive advertising done by this concern would seem to demonstrate its profitableness. On both sides of the Atlantic the public has been advised through the daily and weekly press of the commercial possibilities of "mechanotherapy" as taught by this "college." In commenting on the part that the press plays in making such concerns as this profitable, London *Truth* says:

"It passes my understanding how wealthy newspaper proprietors . . . can condescend to take money for foisting this sort of bunkum on their readers; but as long as they do so, cheap postage to America will certainly put money into some pockets."

Elsewhere the same publication, in describing the "college," calls it "a concern which proposes to give postal tuition in quackery to British fools"—a description which can only be improved by the substitution of "English-speaking" for "British."

Correspondence

Age and Exercise

To the Editor:—I have read with approbation your editorial, "The Septuagenarian Pedestrian," in the issue of August 7. I fully agree that Mr. Weston's performance is "sufficiently noteworthy . . . to deserve mention in a medical journal;" in fact, I go further and assert that it is a demonstration of transcendent importance to all mankind that a man after he is biblically dead, so to speak, having passed his seventieth birthday, can accomplish a feat hitherto considered next to impossible, to-wit, the walking of 3,975 miles in 105 days, or almost 38 miles a day, over, in many cases, execrable roads or on railroad ties, in severe storms, in mud, snow and sleet and sometimes, which is often worse, sand. This great exhibition of human pluck and endurance at an advanced age, is, to my mind, of far more importance than the question of the exact bacillus that causes meningitis, to the discussion of which you cheerfully give up 18⅛ inches of your most conspicuous editorial space, while Mr. Weston's performance gets less than 2½ inches of space, and that at the "tail end," giving one the impression that it is just a "filler." Pardon me if I seem to undervalue your admirable "leader." On the contrary, I enjoyed it and profited by it greatly.

However, my principal object in writing this letter is that I wish to correct one or two erroneous inferences which might readily be drawn from your editorial on pedestrianism. You say that "he [Weston] comes before the public in this spectacular way after about a quarter of a century of comparative obscurity." Among those who take no interest in feats of human endurance, and the improvement of man's physique, Mr. Weston's career for the past twenty-five years may have excited little or no interest. Yet his utterances on temperance and the benefits of exercise have attracted, and deservedly so, considerable attention; and inasmuch as he has participated in a number of pedestrian contests during that period, the sporting element also have had occasion to keep him in mind. In support of this contention, I venture to give a partial list of his performances since 1867:

In 1867 he walked from Portland to Chicago.

In 1868 he walked 100 miles in 24 hours.

In 1870 he walked 100 miles in 21 hours and 39 minutes.

In 1875 he walked 115 miles in 23 hours and 40 minutes without a rest.

In 1879 he walked 550 miles in 141 hours and 44 minutes.

In 1884, under the auspices of the "Church of England Temperance Society," he walked 50 miles a day for 100 consecutive days (Sundays excepted) over English roads, making a total of 5,000 miles, and lectured every night on temperance, of which he has always been an ardent advocate.

In 1886 he walked 2,500 miles against Daniel O'Leary and beat the latter by 200 miles.

In 1893 he walked 160 miles in 39 hours and 59 minutes.

In 1907 he walked from Portland to Chicago in 24 days and 6 hours, beating his own record of 40 years before, by over 16 hours.

He has frequently spoken of his way of life, asserting that he has never taken a drink over a bar. That he eats only twice daily as a rule, and then in great moderation. That he walks 12 or 15 miles every day for exercise, and is consequently always "in condition." He sleeps six hours at night and takes a siesta during the day. Hence it is fair to say that the man is well known, and that the causes of his wonderful endurance are well known. Your editorial concludes with the words that "probably many other men with like training and temperate habits could somewhat approximate his record." A little examination of the subject will show that other men, not to say *women, have already approximated his record.* If you will pardon me, I will take up a little more space to quote a few instances.

Moses Cleveland, a cousin of former President Grover Cleveland, when 82 years old, ran a foot race of a half mile against L. C. Lawrence, aged 80, at Worcester, Mass., and won after an exciting contest by a few yards. Mr. Cleveland declared that he could have run another half mile just as fast as he had won the race, and challenged any man in the world of his age to run a foot race of any distance for any stakes.

Surgeon Major Hinton, who enjoys the distinction of being the oldest member of the Royal College of Surgeons in Great Britain, is in his 95th year. He walks for pleasure 5 miles or more every day. In 1851, Mary Callnack, then 84 years of age, walked from Penzance to London, a distance of nearly 300 miles.

The Emperor Francis Joseph of Austria, at 76 years of age, still stalked "the chamois in its mountain fastnesses."

Timothy Dillon died in New Rochelle, N. Y., in August, 1906, at the age of 100 years. Up to within two days of his death he had taken a daily walk of 4 miles and had formerly walked 20 miles and back twice a week.

Mark All, an Englishman, 78 years of age, had a year or two ago walked 51,751 miles in an attempt to walk 60,000 miles in seven years. A favorite bull dog, after having kept up with his master for 21,000 miles, died.

Hancock says in the introduction of his book on "Exercises for Women," that a teacher of jiu jitsu in Japan, aged 75, vanquished every competitor at this sport who appeared against him.

A Mr. Brown of Philadelphia began playing golf at 50 and at 64 won a tournament, defeating nineteen or twenty competitors, some of whom were thirty years his junior. The newspaper account of this contest says that Mr. Brown had no handicap and won solely on the merits of his play.

A contortionist, aged nearly 80, in perfect health, was looking around a few years ago to find a medical man to whom he could sell his skeleton. He had already disposed of it twice, once to a doctor in Detroit who died, and then to another in New York who had also died.

Mary Wheaton, aged 72, gave not long ago exhibitions of fancy swimming and diving at Bangor, England. She has been an expert swimmer for fifty-seven years.

One hundred thousand miles on a bicycle is the record of Thomas W. Davis of Peoria, Ill., made between the ages of 65 and 75. This includes a number of "century runs," one made when he was 73, in which he outrode a number of younger men.

William O. Greene of Milwaukee, 71 years old, frequently rides 100 miles a day on his "wheel."

"Jem" Mace, the veteran prize fighter, sparred in the ring at 80 years of age. He was noted as a total abstainer.

These are a few records, selected almost at random, from a number collected during the past dozen years or more. No doubt a systematic search would bring to light an indefinite number of similar histories. The point to be noted is that Mr. Weston's record, although remarkable, is by no means unattainable by any faithful pedestrian who is willing to pay the price (1) by long years of constant effort in perfecting himself as a pedestrian; (2) by great abstinence and self-denial, and (3) by sufficient confidence in his own almost limitless powers. Most men lie down and die, not knowing what they are capable of, either mentally or physically. Mr. Weston says that in 1870, when he was preparing to walk 100 miles in twenty-four hours Horace Greeley said to him that it was wicked to encourage him in such an effort, and added: "You are young and spry now, but wait until you are 50 years old and then you can not walk 40 miles a day." No doubt that worthy editor thought he was performing a solemn duty in trying to prevent the rash young man from doing himself a permanent and irreparable injury. Do not wise people still shake their heads and allude to the terrible consequences to be expected in after years if anyone should "over-exert himself" or get 'too tired?" The very indefiniteness of these terms seems to add to their mental picture of the disasters that will follow the disregard of their warnings.

Revolutionary as it may seem, I am prepared to maintain that Mr. Weston, "Jem" Mace, Mr. Cleveland and all the others I have mentioned, have actually lived longer than they otherwise would have done, by reason of their bodily exercises, and not in spite of them. There is no question that college athletes are longer lived than the non-athletic scholars, and if you say that is because they are stronger to begin with than their more sedentary brethren, I deny that. Mr. Weston, like Sandow, Blaikie, Mr. Roosevelt, Dr. Winship and many others, went into physical exercises because they were sickly as boys, and not for pastime.

Fortunately, people are at last beginning to wake up to the paramount necessity of educating and developing the body, and are beginning to perceive that while we are wasteful of many things, we are not so wasteful of any other thing as we are of our own and our children's lives; and, by the way, is it not time that we should drop the use of that unscientific limit to human life so beautifully stated in the Ninetieth Psalm, as it evidently has only a poetical meaning? For that matter, there is just as good biblical authority for placing the limit of our days at 120 years as at 70 years (see Genesis, Chap. vi:3). The former figure, moreover, nearly accords with present scientific opinion as to the length human life should attain than does the latter.

The ignorance and prejudice that surround these all-important questions can scarcely be dispelled until they are approached in a more rational and scientific spirit. While the influence of "the wise old lady next door" is somewhat diminished in clinical medicine, she is still much in evidence in preventive medicine and personal hygiene, as shown, for example, by Mr. Greeley's remarks just quoted in regard to the sad condition in which Mr. Weston would find himself at 50, if he should persist in his dangerous practice of walking. However, the light is slowly breaking as Parkes puts it: "As ages roll on, hope does in some measure grow. In the midst of all our weaknesses, and all our many errors, we are certainly gaining knowledge, and that knowledge tells us in no uncertain language, that the fate of man is in his own hands."

RICHARD COLE NEWTON, M.D., Montclair, N. J.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

TUBERCULOSIS—A BACTERIEMIA?

To the Editor:—In connection with the editorial in THE JOURNAL June 19, 1909, on the theory of tuberculosis as a bacteriemia, in which the results of Forsyth in confirmation of the work of Rosenberger are discussed, as well as Rosenberger's observations, I wish to call attention to a paper by Burnham and Lyons read before the Louisiana State Medical Society, May 4-6, 1909, in which the results of study of ten cases of tuberculosis by the staining methods of Rosenberger, in every case, gave negative results. I note in THE JOURNAL, Aug. 21, 1909, that Ravenel and Smith presented a paper before the Wisconsin State Society in which eighteen cases were studied in the same way with negative results. This subject is one of great interest and in view of the contradictory reports of the observers quoted I think that the question can well be considered doubtful as to whether or not tubercle bacilli are really present in the blood stream. I would like to ask if any other investigators have confirmed or failed to confirm the observations of Rosenberger?

M. P. BURNHAM, Harrisonburg, Va.

ANSWER.—Our correspondent and others may be interested in an article entitled "Tests Concerning Tubercle Bacilli in the Circulating Blood," in the *Archives of Internal Medicine,* August, 1908, ii, 133. The authors, E. C. Schroeder and W. E. Cotton, examined microscopically the blood of forty-two tuberculous cows and bulls, but failed to find tubercle bacilli. The blood from the tuberculous cattle was injected into eighty-eight guinea-pigs, also with negative results.

AIDS TO OBSTETRIC TRACTION BY THE PATIENT

To the Editor:—Sometimes a simple device is of great benefit to humanity. For twenty-four years I have practiced obstetrics: the first four years were times of labor indeed. Any physician who has attended a good strong woman in the second stage of labor, who meant business, and who wished to have her husband, nurse or neighboring women pull on her hands while she was doing her *best to expel* the presenting head, would, it seems to me, welcome the following simple labor-saving device: (1) Take a towel at least 26 inches long and 14 inches wide and catch it by diagonal corners with the thumb and fingers; (2) twist it into a rope; (3) tie the diagonal corners with a square knot—the towel is then converted into a ring with a diameter of 7 inches; (4) fix another towel like the first; (5) place the patient, after the first stage of labor, in the dorsal or lateral prone position with the legs flexed on the thighs; (6) place the rings over the knees and insist that the patient grasp a ring with each hand, while the nurse or some one else keeps the rings from slipping off the knees. The patient is then instructed to pull and hold the breath at the same time. She will recognize after a pain or two, that the rings afford her great comfort, and are an appreciable help in advancing the labor. The use of these rings inspires the patient with confidence in her own strength and her ability to terminate the labor. This device also saves the people in waiting much fatigue, as well as saving the patient from being dragged all over the bed. The device is simple, and always at hand. I have never seen this simple device mentioned in literature.

FRANK DEWITT REESE, Cortland, N. Y.

ANSWER.—In obstetric cases, physicians frequently have to improvise some such simple apparatus as that described above Instead of flexing the knees on the thighs the towels may be placed around the patient's legs, just above the knees, so that she may grasp them as is here suggested and no one need hold them. Another method frequently used is to twist a sheet cornerwise and put it over the crossbar at the foot of the bed, put knots on the ends and let the patient pull on the sheet. Various other simple methods are in common use as well as patented tractors of straps and loops which are more or less complicated. If it will comfort the patient to have something human to hold in place of the effective sheet-rope, let the husband or some one else assist her, but if the medical attendant has tact and firmness it is seldom necessary for him to use up his time and strength *in helping* the patient pull. Our correspondent does not mention the danger that the physician may be so tired and his hands so lamed that he can not give the strength and skill necessary in some complication such as dystocia, retained placenta, hemorrhage, or asphyxia.

NEED OF A SECTION ON PSYCHIC FORCES

To the Editor:—I applaud the call made by Dr. G. Betton Massey, (THE JOURNAL, July 31, 1909, *p.* 394) *for* the establishment of a new "Section on Physical Forces in Medicine and Surgery," and offer an amendment that the new Section embrace the psychic as well as physical forces. I would ask an expression of opinion from the profession.

There is on the part of the people so much unrest and insurrection over the inefficiency of drug therapy which has been indiscriminately prescribed with little or no benefit in a large and rapidly increasing number of cases of nervous disorders that continued neglect of the more effective *psychic and physical* forces for the cure of these disorders will bring disaster to the profession and to the community at large.

Although the development of the psychic forces would perhaps more logically belong to the Section on Nervous and Mental Diseases, the members of that Section have told us so plainly that they are too busy to give the attention to the subject which its importance demands that we must look to new men to develop it, and besides it is a subject on which the general practitioner of the future will have to be educated, and, all things considered, I believe that the best possible way to develop the psychic and physical forces which will in the future play an increasingly important part in the healing art is to organize a new Section, which in my judgment will not be lacking in earnest work and hearty support at any meeting.

GUSTAVUS WERBER, Washington, D. C.

CHEESE IN TREATMENT OF CELLULITIS

To the Editor:—Recently I had a case of cellulitis of the hand with badly engorged lymphatics and ascending phlegmonous manifestations. The hand was swollen, the arm brawny and swollen. I made free incisions in the hand, applied hyperemic cups and arm band, and soaked the parts for hours in hot bichlorid of mercury. The arm was getting along well, but one day I noticed it white and the skin loose and apparently bloodless. The patient said that on the entire arm he had placed the ordinary *fresh* cottage cheese—*Schmierkäse* of the Germans—and the benefit seemed more than that obtained from the Bier treatment, incisions and bichlorid of mercury. I would like to know from what source the benefit was derived. Unfortunately, I made no *microscopic* examination of the pus, but my own *explanation* was that the lactic and butyric acid organisms must have had an inhibitory or bacteriolytic *action on those pus organisms. Can you tell me if this is so?* Is there any literature on the subject? Or did the bactericidal serum or opsonins of the body simply overcome the invading organisms? Cheese is a household remedy among the Slavs for pneumonia, erysipelas and any local infection, and, strange to relate, it works.

C. E. McDERMID, Charleroi, Pa

ANSWER.—The application of cheese is of little if any benefit. It is true that fresh green cheese contains many lactic acid bacteria, but usually the ordinary kind; and it would be rather difficult for these bacteria to reach the seat of the trouble. It is not impossible that the application of the cheese had a similar effect to that of a moist poultice. The statement that Slavs use cheese for pneumonia and erysipelas successfully is rather indefinite; many popular ideas are devoid of scientific basis and should be mistrusted It is probable that the supposed benefit derived from application of cheese is purely coincidental.

PHOSPHORESCENT SIGNS FOR PHYSICIANS

A correspondent states that some years ago an agent sought to sell him a sign for his office to contain his name in phosphorus letters, so that in the day time it would appear as a plain white sign, but at night would shine with a phosphorescent glow. He asks the name and address of any firm that makes such signs, and we will be glad to pass the information on to him if any of our readers can inform us.

The Public Service

Medical Department of the Army

Memorandum of changes for the week ended Aug. 21, 1909:

Robbins, Chandler P., major, granted leave of absence for one month.

Reynolds, Charles R., major, granted leave of absence for 10 days.

Russell, F. F., major, ordered to proceed from Washington, D. C., to Fort Sill, Okla., and return, on business connected with the Medical Department.
